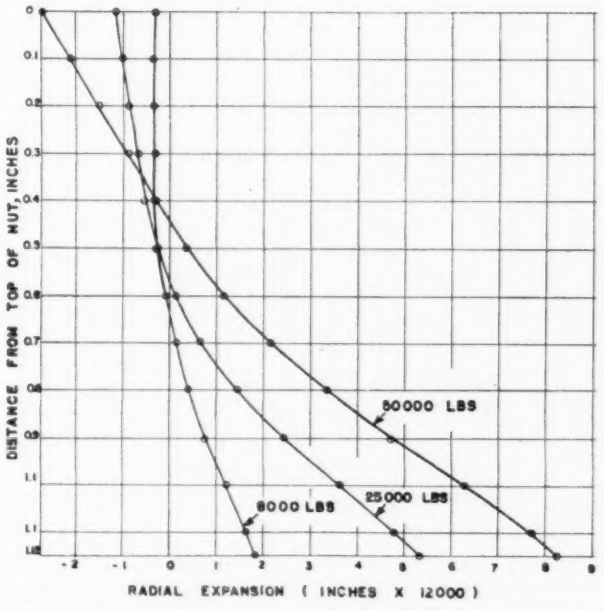

FIG. 3 RADIAL EXPANSION OF A NUT WITH 1¹/₄-IN. AMERICAN STANDARD THREAD, THIRD SPECIMEN

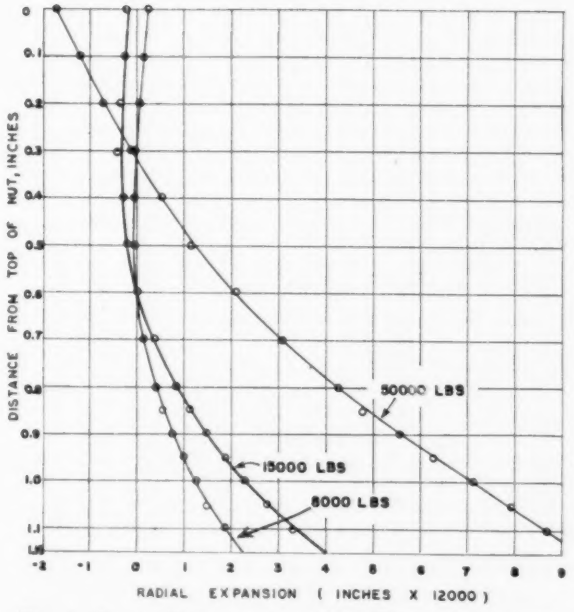

FIG. 4 RADIAL EXPANSION OF A NUT WITH 1¹/₄-IN. ACME THREAD

shown in Fig. 7. It will be observed that there are no such striking differences for these different positions as were found in the case of the radial displacement.

INSTRUMENTS

Measurements of v were made with the mirror extensometer shown in Fig. 8 which was designed for this purpose. It is essentially a modification of E. H. Lamb's (4) roller extensometer for lateral measurements. That instrument has a movable block separated from the "fixed" member by steel balls in grooves and fine rollers the rotation of which is observed optically; the movable block takes the displacement to be measured. In the modification, the movable block B, shown in Fig. 8, is attached to the fixed member by arch springs which simplifies construction. Tilting of the block during displacement, due to inequality of the springs, is allowed for by providing mirrors and their optical levers at each end of the rollers. The rotation of each end is thus measured separately. The rollers were about 5 in. between grips and 0.04 in. diameter, so that any slight difference between the end rotations could easily be accommodated by torsion. The average of the two measurements gives the translation of the block.

The axial displacements u were measured with a Martens extensometer, one end of each comparison strip being mounted on a light dummy cylinder continuing the nut surface, but attached

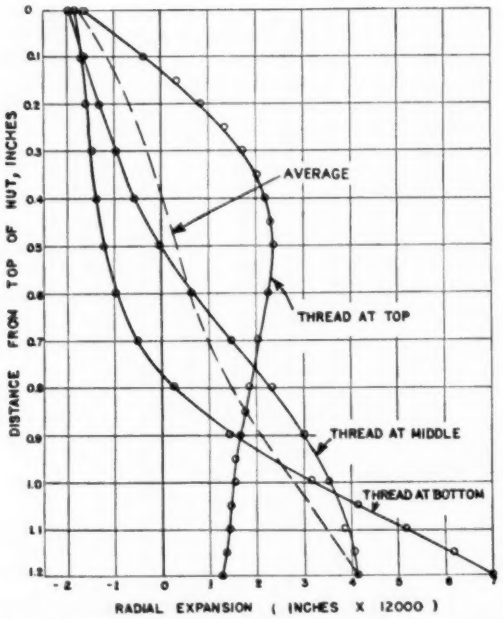

FIG. 5 RADIAL EXPANSION OF A NUT WITH 1¼-IN. AMERICAN STANDARD THREAD, RUN ON A BOLT WITH ONLY A SINGLE TURN OF THREAD

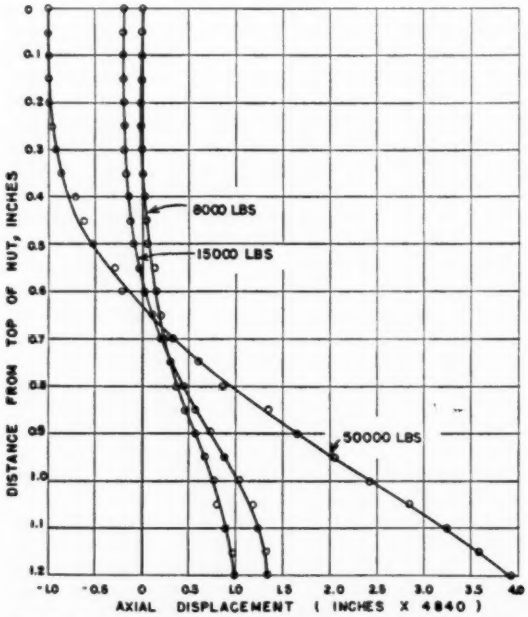

FIG. 6 AXIAL DISPLACEMENTS OF THE SURFACE OF A NUT WITH 1¼-IN. AMERICAN STANDARD THREAD

to the nut at two points only, so that it showed no axial strain within its own length on loading the nut and bolt.

Observations were recorded only after a number of preliminary loadings, sufficient to reach a steady loading-unloading cycle. The instruments were moved from one position to the next, up or down the nut, while a load remained to prevent shifting of the nut. Loading was then repeated three or four times in each position to confirm the steady state.

CALCULATION OF LOAD DISTRIBUTION FROM DEFORMATION

Even when yielding has occurred at the root of the thread, the major part of the nut wall is still elastic. We may therefore

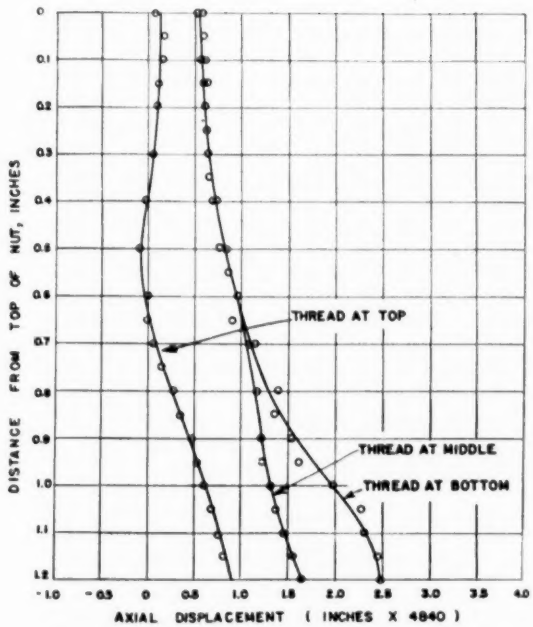

FIG. 7 AXIAL DISPLACEMENTS OF THE SURFACE OF A 1¼-IN. AMERICAN STANDARD NUT RUN ON A SINGLE-THREAD BOLT

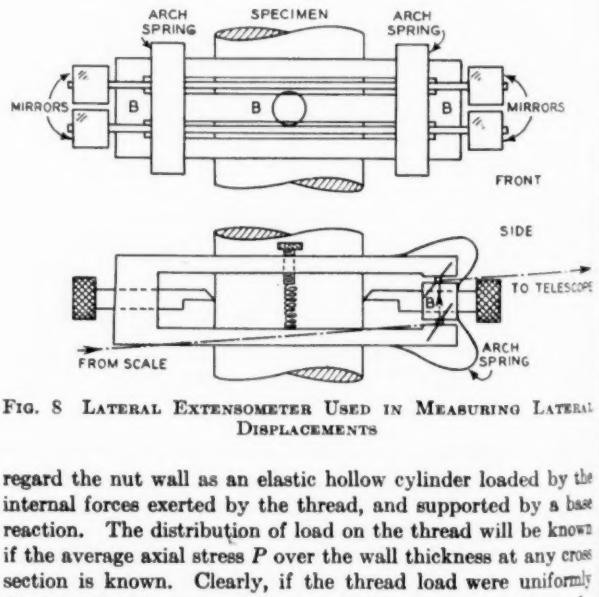

FIG. 8 LATERAL EXTENSOMETER USED IN MEASURING LATERAL DISPLACEMENTS

regard the nut wall as an elastic hollow cylinder loaded by the internal forces exerted by the thread, and supported by a base reaction. The distribution of load on the thread will be known if the average axial stress P over the wall thickness at any cross section is known. Clearly, if the thread load were uniformly distributed, this average stress would increase linearly from the top (where it is zero) to the base.

The expression for P in terms of u and v is

$$P = -\frac{J}{\omega}\left\{ e^{m_1 x}\int_0^x [Sm_1{}^3u + (K - Lm_1{}^2)v]e^{-m_1 x}\,dx \right.$$

$$- e^{m_2 x}\int_0^x [Sm_2{}^3u + (K - Lm_2{}^2)v]e^{-m_2 x}\,dx$$

$$\left. -L\omega v + S(m_1{}^2 - m_2{}^2)u + S\omega(du/dx) + Be^{m_1 x} + Ce^{m_2 x} \right\} \quad \ldots\ldots[1]$$

The derivation, and the values of the coefficients, are given in Appendix 1; B and C are constants of integration to be adjusted

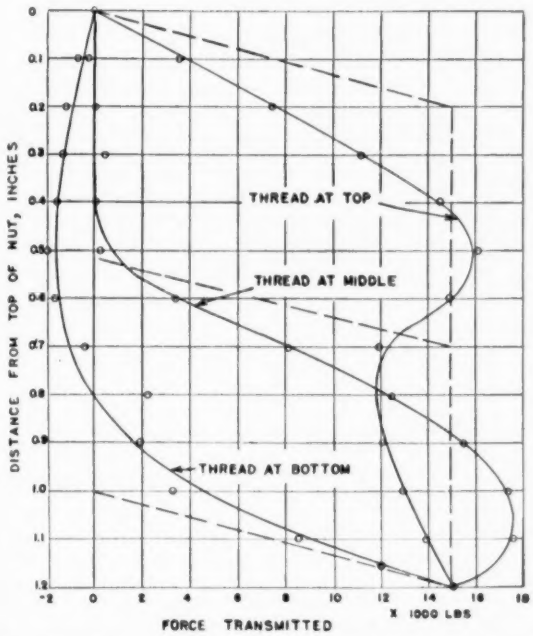

FIG. 9 FORCE TRANSMITTED TO A 1¹/₄-IN. AMERICAN STANDARD NUT AS A FUNCTION OF THE AXIAL COORDINATE, CALCULATED FROM OBSERVED DISPLACEMENTS WHEN THE NUT WAS RUN ON A SINGLE-THREAD BOLT

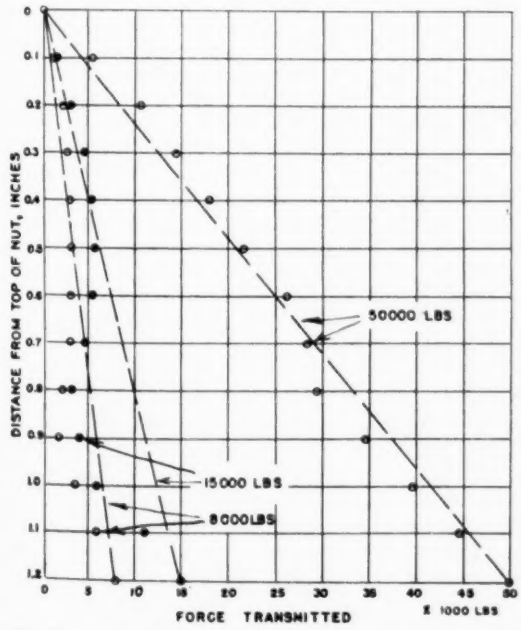

FIG. 10 VALUES OF P FOR 1¹/₄-IN. AMERICAN STANDARD NUT WITH ORDINARY BOLT, CALCULATED FROM FIG. 1

to make P take the required values at the free end (zero) and the base.

This relation was tested by applying it to the u and v curves obtained with the single-thread bolt. In that case the value of P should be zero from the top as far as the loaded thread of the nut, then take within the space of this thread the full value (the load divided by the cross-sectional area of the wall), and retain this value down to the base.

The results actually obtained are shown in Fig. 9. In view of the almost discontinuous character of the loading, and assumptions involved in Equation [1], the indications of Fig. 9 are surprisingly good. Approximate true curves are shown as broken lines.

Curves for several nuts with ordinary bolts, calculated from Figs. 1, 2, 3, and 4 by means of Equation [1], are shown in Figs. 10, 11, 12, and 13. Comparison with Fig. 9 leaves no doubt that there is no concentration of load at the top or middle. While the method is evidently not sufficiently accurate to determine the actual distribution, especially at the lower loads, it indicates substantially uniform loading at 50,000 lb, and a tendency to concentration at the base for the lower loads. The average stress in the bolt core at 50,000 lb is 56,000 lb per sq in., and at 8000 lb it is 9000 lb per sq in. The steel used was Bessemer screw stock S.A.E. 1112 with a yield point at 80,000 lb per sq in.

TYPES OF FLEXIBILITY AFFECTING THE LOAD DISTRIBUTION

The deformation as a whole may be resolved into the following three principal types: (*a*) Axial contraction of the nut wall and extension of the bolt core; (*b*) bending of the two threads as cantilevers; and (*c*) circumferential stretch of the nut wall. The curves in Figs. 1, 2, 3, and 4 enable us to estimate the relative importance of these types in governing the load distribution, and thus to judge the probable value of modifications designed to reduce the concentration.

The axial contraction of the nut, and the antagonistic extension of the bolt within the nut, have to be reconciled by means of other types of deformation, since thread contact requires the same deformation of nut and bolt along the bearing surfaces of the two threads. Type (*a*) is thus primarily responsible for the concentration. In fact it may be shown that by itself it would cause complete concentration on an infinitesimal length of thread at the base; or a concentration at *each* end of the thread in the case of the turnbuckle type of screw connection.

The calculations of Den Hartog (3) and Jaquet (1) show that thread bending is adequate to change this to a smooth distribution although still with a severe concentration at the base. Circumferential stretch of the wall, as will appear, has an effect similar to that of thread bending. It creates effectively an *axial* tensile strain at the threads, offsetting the compressive strain in the nut wall. The types (*b*) and (*c*) thus moderate the extreme concentration due to (*a*).

In comparing the effects of these different types of flexibility we may suppose that the thread of the bolt is in contact with that of the nut along the helical middle lines of the active thread surfaces. Let u_b denote the axial displacement of a point of this line on the bolt thread, at a distance x from the base, and let u_n be the displacement of the corresponding point on the nut thread.

The condition of contact is expressed by $du_b/dx = du_n/dx$.

All types of flexibility which contribute significantly to either of these two derivatives, that is, to the relative axial displacements of points on one thread or points on the other, under the actual load distribution, are important in determining the distribution.

Considering the nut only, it is clear that flexibility of type (*a*) contributes to du_n/dx an amount P/E. We may represent the order of magnitude of this by its greatest value.

The bending of the thread as a cantilever depends on the load per unit run of thread. From x to $x + \delta x$ there is a length $2\pi nr\delta x$ where n is the number of turns of thread per unit axial length and r their mean radius. The axial load carried corresponds to the increase in P and is $A(dP/dx)\delta x$, where A is the cross-sectional area of the nut wall. The axial load per unit run of thread is thus $(A/2\pi nr)(dP/dx)$, and the deflection is $\beta(A/2\pi nr)(dP/dx)$, where β is an elastic coefficient depending on the shape and material of the thread. The contribution to du_n/dx is the derivative of this, or $(\beta A/2\pi nr)(d^2P/dx^2)$.

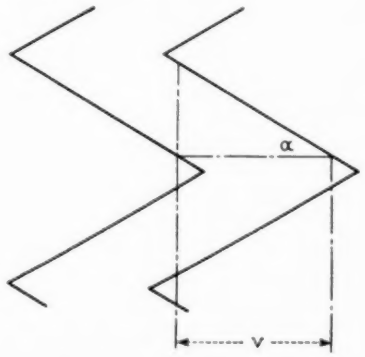

FIG. 14 THREAD RECESSION

In order then to estimate the contribution of type (*b*) directly we should require an estimate of d^2P/dx^2, but such an estimate cannot be made without an accurate knowledge of the load distribution. The contribution can however be estimated indirectly. If the distribution were determined entirely by the flexibilities (*a*) and (*b*), their contributions would necessarily be of the same order of magnitude. Since the actual distribution is certainly more uniform than it would thus be, we shall be overestimating rather than underestimating the effect of the thread bending if we assign to it the same order of magnitude as to axial strain, that is, P/E.

The contribution of circumferential stretch divides into two parts, in the case of V or acme threads. If we imagine a point of contact between the two threads, then allow the nut thread to move radially outward by a distance v, shown in Fig. 14, it is clear that this movement creates a vertical gap $v \tan \alpha$ between the two threads. If v were uniform from top to bottom of the nut, the bolt would merely have to descend bodily the distance $v \tan \alpha$ in order to reestablish contact. But if v should not be uniform, contact could not thus be made along the whole thread. The effect of a nonuniform v is evidently expressed by a contribution $\tan \alpha(dv/dx)$ to du_n/dx. The order of magnitude of this is easily estimated from the v curves of Figs. 1, 2, 3, and 4. It will be referred to as "thread recession." It is partly due to the lateral expansion accompanying the compressive axial stress, and partly to the radial component of the thread load.

The other effect of the circumferential stretch, or radial displacement, comes from the axial curvature involved, a strip of the nut between two neighboring planes through the axis being in the condition of a bent beam with curvature d^2v/dx^2. The contribution to du_n/dx corresponds to the tensile strain, in such a beam, of points at a distance s from the neutral axis, where s may be taken as the distance from the middle of the thread to the middle of the nut wall. Its magnitude is then sd^2v/dx^2.

The curves of Figs. 1, 2, 3, and 4 are sufficiently well defined by the observed points to permit a satisfactory estimate of the order of magnitude of d^2v/dx^2.

Estimating the orders of magnitude of these four contributions to du_n/dx in the ways indicated, for the $1^1/_4$-in. nuts, and for a load of 15,000 lb,[4] we have the values given in Table 1

TABLE 1

Type of flexibility	Order of magnitude of effect on load distribution, measured by contribution to du_n/dx
(*d*) Simple axial strain	30×10^{-5}
(*e*) Thread bending	30×10^{-5}
(*f*) Thread recession	up to 50×10^{-5}
(*g*) Wall bending	up to 40×10^{-5}

The conclusion is therefore that all four effects given in Table 1 are about equally important. The first type of flexibility being the real source of concentration, and the other three being moderating influences, the actual distribution, even without any yielding at the roots of the threads, will be considerably more uniform than that determined by neglecting types (*f*) and (*g*).

Means for Reducing the Concentration of Load

It is evident that any modification which increases any of the types of flexibility (*e*), (*f*), or (*g*) will have a favorable effect.

Any reduction of wall thickness will be effective in this way, but it will at the same time increase the undesirable flexibility of type (*d*). The bending flexibility, however, is likely to be more sensitive to reduction of thickness than the axial compressibility. Jaquet (1) describes a modification of the usual thread, due to J. R. Solt, in which the thread is undercut into the wall, so that the thread depth is increased at the expense of the wall thickness. There is then a gain of flexibility of all four types. Another modification, essentially a reduction of wall thickness at the base, has been tested in fatigue by H. Wiegand (5).

Reduction of friction between thread and thread, and between the base of the nut and its support, should improve the distribution by permitting more radial expansion.

Since the axial bending of the wall must be influenced by the clamping of the base of the nut against its support, there is a possibility of improving the distribution by rounding the base of the nut, so that its contact with the base is over a circle instead of a wide annulus. There would then be an approach to zero bending moment M_1 (see Appendix 1), at the base.

The bending flexibilities of types (*f*) and (*g*) can be somewhat increased, without increasing the axial compressibility (*d*), by making axial cuts into the wall of the nut from the outside.

Increasing the fineness of the thread would appear to decrease the favorable flexibility of type (*e*), for geometrically similar beams have the same deflection per unit width and unit load, and since the finer thread has the greater "width" (helical length), its deflections would be smaller under the same load distribution. In the expression $(\beta A/2\pi nr)d^3P/dx^2$, which measures the contribution of this type of flexibility to du_n/dx, β remains the same, but n, the number of turns per inch, is greater, so that this desirable contribution is reduced.

Appendix 1

The Load on the Thread in Terms of the External Deformation of the Nut

To obtain the relation in question we may consider the condition of an element of the wall of the nut contained between cross-sections x and $x + \delta x$ from the free end, and by two planes through the axis including an angle $\delta\theta$ as shown in Fig. 15. The thread is not included in this element. The forces acting on it are supposed transferred unchanged to the internal wall surface. At the section x there will be an average compressive stress P, so that if A is the cross-sectional area, AP represents the load carried on the thread above the cross section. Then $[d(AP)/dx]\delta x(\delta\theta/2\pi)$ or $(A/2\pi)(dP/dx)\delta x\delta\theta$ represents the vertical component of thread load on the element. The actual force on the thread will also have a horizontal radial component, tan $(\alpha - \phi)$ times this vertical component, if α is the semiangle of the thread and ϕ is the angle of thread friction.

[4] The *relative* orders of magnitude are similar for other loads.

The forces exerted by the thread on the inner wall of the nut are statically equivalent (approximately) to the pressures on the thread. Thus, we may place the thread forces on the element at their actual position as if the thread were there, as is done in Fig. 15.

Let the axial stress form, in addition to the average stress P, a bending moment M_1 per unit length of mean circumference, positive in the sense shown in Fig. 15. There will also be radial shearing force F per unit of mean circumference.

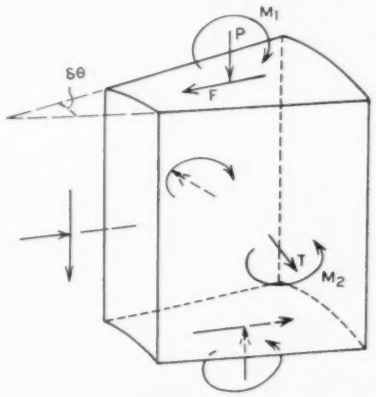

Fig. 15 Element of a Nut Wall

On the faces in the axial planes there will be an average tensile stress T, and a bending moment M_2, positive as shown, per unit axial length. We assume symmetry of the stress and strain about the axis, so that there will be no shearing force.

The equations of equilibrium of the element are then

$$T = \rho \tan (\alpha - \phi) \frac{dP}{dx} + \rho \frac{dF}{dx}$$

$$\rho F = -\frac{\rho}{2h}\frac{dM_1}{dx} - \rho s \frac{dP}{dx}$$

where ρ is the mean radius, $2h$ the wall thickness, and s the radial distance between the load line on the thread, and the middle surface between walls. The neutral axis of bending for the element is taken at the mean radius.

Eliminating F

$$T = \rho \tan (\alpha - \phi) \frac{dP}{dx} - \rho s \frac{d^2P}{dx^2} - \frac{\rho}{2h}\frac{d^2M_1}{dx^2} \quad \ldots\ldots [2]$$

The curvature of generators of the cylindrical surfaces may be ascribed to both bending moment M_1 and shear F. If we consider the complete ring between x and $x + \delta x$, it is clear that the deformation due to F will not alter the circumferential curvature appreciably. If M_2 were wholly due to the prevention of the anticlastic curvature of M_1, we should have $M_2 = \sigma M_1$, where σ is Poisson's ratio, neglecting the difference between the shapes of the elementary areas on which M_1, M_2 are found.

A radial displacement v of the mean radius ρ involves a change v/ρ^2 in the circumferential curvature. But there is a radial displacement due to P alone of amount $\sigma P\rho/E$, where E is Young's modulus, and thus a change of curvature $\sigma P/E\rho$. Thus M_2 must prevent the anticlastic curvature of M_1, and in addition produce curvature $v/\rho^2 - \sigma P/E\rho$. Hence

$$M_2 = \sigma M_1 + \frac{2}{3}Eh^3\left(\frac{v}{\rho^2} - \frac{\sigma P}{E\rho}\right) \quad \ldots\ldots [3]$$

a linear distribution of axial stress across the wall thickness being assumed.

The stress-strain relations for an element on the outside wall are

$$\left.\begin{aligned} P + \frac{3}{2}\frac{M_1}{h^2} &= \frac{E}{1-\sigma^2}\left[\frac{du}{dx} - \sigma\frac{v}{b}\right] \\ T - \frac{3}{2}\frac{M_2}{h^2} &= \frac{E}{1-\sigma^2}\left[\frac{v}{b} - \sigma\frac{du}{dx}\right] \end{aligned}\right\} \quad \ldots\ldots\ldots [4]$$

where u is the axial displacement relative to and toward the base, x being measured upward from the base, and b is the outside radius.

Now, M_1, M_2, and T can be eliminated from Equations [2], [3], and [4], the result being

$$\frac{d^2P}{dx^2} + G\frac{dP}{dx} + HP = f(x) \quad \ldots\ldots\ldots\ldots [5]$$

where

$$f(x) = \frac{1}{\rho\left(s - \frac{1}{3}h\right)}\frac{E}{1-\sigma^2}\left\{\frac{\rho\sigma h}{3b}\frac{d^2v}{dx^2} - (1-\sigma^2)\left(1 + \frac{bh}{\rho^2}\right)\frac{v}{b} - \frac{\rho h}{3}\frac{d^3u}{dx^3}\right\}$$

$$G = -\frac{\tan(\alpha - \phi)}{s - \frac{1}{3}h}$$

and

$$H = -\frac{\sigma(\rho + h)}{\rho^2\left(s - \frac{1}{3}h\right)}$$

The solution of Equation [5] is

$$P = \frac{1}{m_1 - m_2}\left\{e^{m_1 x}\int_0^x e^{-m_1 x} f(x)dx - e^{m_2 x}\int^x e^{-m_2 x} f(x)dx + Be^{m_1 x} + Ce^{m_2 x}\right\} \ldots [6]$$

where m_1 and m_2 are the roots of $r^2 + Gr + H = 0$, and B and C are arbitrary constants. The function $f(x)$ involves the derivatives d^2v/dx^2 and d^3u/dx^3. It would of course be impossible to derive these satisfactorily from the observations, but they can be removed by partial integrations, the final form for P being given by Equation [1].

The constants appearing in that equation are as follows

$$\omega = m_1 - m_2,$$

$$J = \frac{1}{\rho\left(s - \frac{1}{3}h\right)}\cdot\frac{E}{1-\sigma^2} \qquad L = \frac{\rho\sigma h}{3b}$$

$$K = (1-\sigma^2)\left(\frac{1}{b} + \frac{h}{\rho^2}\right) \qquad S = \frac{\rho h}{3}$$

There are no surviving derivatives of u and v except du/dx, which was obtained by graphical differentiation. The integrals were evaluated from the u and v curves by Simpson's rule, and the constants B and C adjusted to make P take the required free end and base values—zero and the full-load value, respectively. The coefficient of friction, involved in m_1 and m_2 was measured by turning the nut or the bolt, under small loads, and found to be about 0.3. It is assumed in the analysis of course that friction has its limiting value throughout.

Appendix 2

Concentration of Load at the Base, and Saint-Venant's Principle

If the base of the nut is taken as fixed, the strain energy of nut and bolt above the base is represented by the work of the stress in the base cross section of the bolt, acting over the displacements in that section. The edges being fixed, through thread contact at the base of the nut, these displacements consist of a deformation of the section.

The stress is of order of magnitude P, the average tensile stress of the bolt. The elastic strains (including those of the threads, since thread strength and bolt strength are comparable) are of order P/E, and consequently the displacements in the base section of the bolt are of order Pr/E where r is the radius. The work done on these displacements will thus be of the order of the resultant $P\pi r^2$ multiplied by Pr/E, or $P^2\pi r^3/E$.

Where the stress is appreciable it is of order P and involves strain energy of order P^2/E per unit volume. The work actually done, $P^2\pi r^3/E$, is then adequate for a volume of order πr^3, or for a distance of order r from the base, whatever the length of the nut.

This argument[5] is substantially an application of Saint Venant's principle to the portion of the nut and bolt above the base, the forces on the complete base section forming a self-equilibrating system.

[5] The Principle of Saint Venant in its usual form may be established in a similar way (*Philosophical Magazine*, April, 1937, and August, 1937).

Stresses and Deflections of Three-Dimensional Pipe Bends

By H. PORITSKY[1] and H. D. SNIVELY,[2] SCHENECTADY, N. Y.

Many treatments of stresses of three-dimensional pipe bends have appeared in recent times.[3,4] While the calculation of these stresses and deflections is perfectly straightforward, it is still very complicated. It is believed that the analogy to which attention is called in this paper should be of considerable assistance in simplifying these calculations by pointing out their similarity to familiar dynamical concepts involving products and moments of inertia and moments of momentum.

Tractions and Displacements of a Curved Beam Loaded Terminally

CONSIDER a curved beam. Suppose that there is no load on the beam throughout its length, but that it is subjected to tractions over its ends. Let s be the arc length of (the middle line of) the beam and let s_1, s_2 correspond to its two ends P_1, P_2. At a point P corresponding to any value of s, let $\boldsymbol{F}$ be the resultant vector force and $\boldsymbol{M}$ the vector moment of the traction which is exerted by the portion of the beam to the positive side of the section (corresponding to larger s) upon the portion to its negative side. The moment $\boldsymbol{M}$ is calculated with respect to the center of gravity of the cross section of the beam. Applying equilibrium conditions to the beam section between P_1 and P, there results

$$\boldsymbol{F} = \boldsymbol{F}_1,\ \boldsymbol{M} = \boldsymbol{M}_1 + (\boldsymbol{F}_1 \times \boldsymbol{r}) \quad [1]$$

where $\boldsymbol{r}$ is the radius vector P_1P and $\boldsymbol{F}_1$, $\boldsymbol{M}_1$ are the resultant force and moment of the tractions at P_1.

These tractions produce a certain distortion and displacement which result in a motion of one end of the pipe relative to the other one. In fact, it is the displacement of one end relative to the other one that is sometimes the cause of the whole set of forces. In order to calculate this displacement, it is assumed, as is common in the theory of thin beams, that the effect of the compressional or shear components of the resulting traction $\boldsymbol{F}$ is negligible in producing distortions and displacements as compared with the effect of the moment $\boldsymbol{M}$. This moment may be resolved along the tangential direction as well as along the two principal moment directions of the normal section. The first component of the moment is a twisting component which tends to produce torsion in the pipe; the other two components are bending components. If β_1, β_2, β_3 represent the twisting and bending flexibilities of the pipe along its tangential and principal moment normal directions, respectively, and if m_1, m_2, m_3 represent the components of $\boldsymbol{M}$ along these three directions, then the vector

$$\boldsymbol{R} = (\beta_1 m_1,\ \beta_2 m_2,\ \beta_3 m_3) \quad [2]$$

represents the rotation per unit length of pipe; thus, multiplied by ds, it yields the rotation of the section at $s + ds$ relative to the section at s. The sense in which $\boldsymbol{R}ds$ represents the rotation is that the rotation axis points along $\boldsymbol{R}$ while the magnitude of the angular displacement is equal to the length of this vector. In representing rotational displacements of space by means of vectors in this fashion, it must be borne in mind that this is only correct when the displacements are small. This, however, is the usual assumption made in elasticity and it will be adhered to throughout this paper.

Suppose now that the three flexibilities are equal one to the other and are represented by β; then

$$\beta_1 = \beta_2 = \beta_3 = \beta \quad [3]$$

The latter need not be assumed, however, to be constant over the whole pipe length. The flexibilities for a pipe of circular cross section are $\beta_1 = 1/GJ$, $\beta_2 = \beta_3 = 1/EI$, where E is Young's modulus, G is the shear modulus, J is the polar moment of inertia of the cross section, and I is the plane moment of inertia about a diameter. Since

$$G = \frac{E}{2(1+\sigma)},\ J = 2I \quad [4]$$

it will be seen that for a circular pipe

$$\beta_2 = \beta_3 = \frac{\beta_1}{1+\sigma} \quad [5]$$

The assumption of Equation [3] is therefore not too erroneous for a circular cross section.

Under the assumptions of equal flexibilities the rotation vector may be replaced simply by

$$\boldsymbol{R} = \beta \boldsymbol{M} \quad [6]$$

where $\boldsymbol{R}$ is the rotation per unit length. (Compare Equation [6] with the familiar beam equation, $y'' = M/EI$.)

Consider next the displacement of the beam (center line) which occurs as a result of the rotation implied in $\boldsymbol{R}$. If the end s_1 is, for definiteness, held fast, then various sections will suffer both rotational and translational displacements relative to this end section. In particular, the end s_2 will have a net angular rotation relative to s_1 represented by the rotation vector

$$\int_{s_1}^{s_2} \boldsymbol{R}ds = \int_{s_1}^{s_2} \beta \boldsymbol{M}ds \quad [7]$$

since the resultant rotation vector due to several rotations along different axes may be obtained by vector addition of the individual rotation vectors irrespective of where they are located.

The translation of the end s_2 relative to the end s_1 is (again on the assumption of small displacements) given by

$$\boldsymbol{D} = \int \boldsymbol{R} \times (\boldsymbol{r}_2 - \boldsymbol{r})ds \quad [8]$$

Presented at the Annual Meeting, Philadelphia, Pa., December 4–8, 1939, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

In Equation [8] the origin of r has again been assumed to be at s_1.

The foregoing formulas allow the computation of the displacement of one end relative to the other one to be carried out in a straightforward manner. While the calculation is simpler than, say, by means of Castigliano's theorem, it is still fairly complex. It is the object of the following portion of this paper to point out an analogy between the foregoing discussion and a simple problem in dynamics of rigid bodies which can be used to simplify the problem and reduce it to more familiar terms.

Analogy Between the Beam Problem and a Dynamical Problem

To formulate this analogy, consider the state of velocities existing at any instant during the general motion of a rigid body, as shown in Fig. 1. In a translation the velocities are everywhere

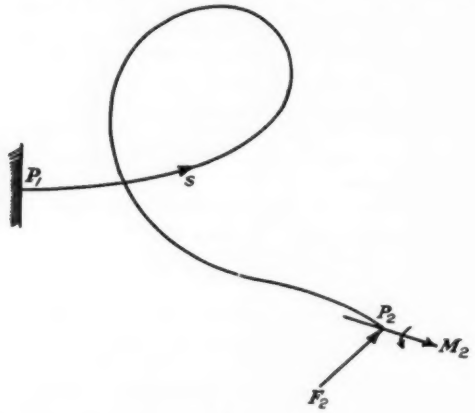

Fig. 1

equal to the same vector which may be used to represent the translation. In a rotation about an axis through the origin, the velocities are given by

$$v = w \times r \quad [9]$$

where w is the "rotation vector," that is, the vector whose length is proportional to the angular velocity of rotation and whose direction is along the axis of rotation and is chosen so that a right-handed screw rotating in the sense of the rotation under consideration will advance along the direction of the vector.

It may be shown that the most general set of velocities of a rigid body may be considered as a superposition of a translation and a rotation about a proper axis with a proper angular velocity. This resolution into a rotation and a translation can be carried out in a great variety of ways. Picking any one point, one may carry out the resolution by using a translational velocity which is equal to the velocity of that point; then, the additional rotation will consist of a rotation about some axis through that point. If different points are used, the translational velocities will, in general, not be the same. However, the rotation vectors which represent the rotational velocities turn out to be the same in magnitude and direction. If the state of velocities has been reduced in the previously described manner with respect to the point P which is taken at the origin, then the velocity of any point of space turns out to be given by

$$v = v_0 + (w \times r) \quad [10]$$

Now turn to the statics of forces acting on a rigid body. As is well known, any system of forces can be reduced to a single force F through a given point and a proper "couple." The latter may be visualized as a pair of equal and opposite forces not along the same line, but it is more conveniently represented by means of its vector moment M about any point of space, since this M turns out to be the same irrespective of the point about which it is taken. Again, any two couples with the same moment are equivalent to each other.

At this stage the familiar analogy between the reduction of velocities of a rigid body and the reduction of equivalent systems of forces becomes clear. A force in the one case is analogous to a rotation vector in the other case, while a couple (or rather, its moment M) is analogous to a translation. The velocity of a point corresponds to the moment of the forces. A system of forces corresponds to a set of rotations which take place simultaneously about various axes, the resultant velocity of any point being the sum of the velocities due to each rotation separately. The fact that two equal and opposite forces acting along parallel lines have a resultant zero and a moment which is constant in magnitude and direction no matter about what point it is taken, now has its analog in the fact that two equal and opposite rotations which take place simultaneously about two parallel lines result in a translation of the rigid body in question.

In the foregoing analogy it will be noticed that forces do not correspond to translations, but rather to rotation vectors, while the moments (of couples) correspond to translations rather than rotations that one would naturally associate with moments of couples or torques. This may be further justified by noting that the point of application of a force could not be moved at random but only along its line of action while the moment of a couple could; similarly, the position of the rotation vectors may be moved along a line of rotation but in no other way, since the rotation about one axis is obviously not equivalent to a similar rotation about a different axis in that it produces different velocities in the body.

Suppose now that the beam is freed at each end and, considered as a rigid body, is given a motion possessing velocities due to a translation M_1 plus velocities due to a rotation about the center of the initial section s_1 represented by the rotation vector F_1. Then the velocity of any centerline point P with arc length s (see Equation [10]) is given by

$$v = M_1 + (F_1 \times r) \quad [11]$$

TABLE 1 SUMMARY OF THE ANALOGY

Stress and deflection in the beam	*Motion of the beam*
M = vector moment of tractions across a section at P.	v = velocity of center point of section at P.
F = resultant force across section at P.	w = rotation vector of the beam motion.
β = flexibility.	β = mass per unit length.
R = rotation vector per unit length of beam.	$R = \beta v$ = momentum per unit s.
$\int_{P_1}^{P_2} Rds$ = vector representing rotation of section at P_2 relative to P_1.	$\int Rds$ = momentum of section between P_1 and P_2.
D = displacement of section at P_2 relative to P_1 when the beam section at P_1 is held fast.	D = moment of momentum of section P_1P_2 about P_1

and if the motion is reduced with respect to s, it will be resolved into a translation of velocity given by Equation [11] and a rotation about P represented by the rotation vector

$$w = F_1 \quad [12]$$

This is an instance of the foregoing analogy and shows that the calculation of the traction across any section, as represented by M and F is completely equivalent to the resolution of the velocities of the beam when properly moving, with respect to any point along its center line.

Examining Equations [7] and [8], it will now be noted that the analogy may be taken further. Indeed Equation [7] is seen to be the total (vector) momentum of the beam moving as previously specified, provided β is taken as the mass per unit length of the central axis. Since $R \times (r_2 - r)ds$ is the moment of the vector Rds about P_2, it follows that D as given by Equation [8] is completely analogous to the moment of momentum of the moving rigid beam about P_2.

The analogy is summarized in Table 1, which appears at the bottom of the preceding page.

Further Discussion of the Analogy

In utilizing the foregoing analogy, it is convenient to recall familiar facts regarding momenta and moments of momenta, such as the following three:

1 The momentum of any system of particles (whether they constitute a rigid body or not) is equal to the momentum obtained by transferring the total mass to the center of gravity and having it move with the velocity of the center of gravity.

2 The moment of momentum of a rigid body moving in any manner, about a point P, is the sum of the moment of momentum about P which results when all the mass is transferred to the center of gravity and allowed to move with its velocity plus the moment of momentum about the instantaneous position of the center of gravity due to rotation of the rigid body relative to the center of gravity. The phrase "motion relative to the center of gravity" refers to the fact that if the velocities of the rigid body be resolved with respect to the center of gravity, they will consist of two parts, namely, a constant translational velocity equal to the velocity of the center of gravity plus a state of velocities due to a proper rotation about some line through the center of gravity. It is the latter component which may be described as the part of the velocity "relative to the center of gravity."

3 The moment of momentum of a rigid body due to a motion of rotation represented by the rotation vector

$$w = w_x i + w_y j + w_z k \quad [13]$$

is given by

$$\begin{aligned}&(w_x I_x - w_y I_{xy} - w_z I_{xz})i \\ &+ (-w_x I_{xy} + w_y I_y - w_z I_{yz})j \\ &+ (-w_x I_{xz} - w_y I_{yz} + w_z I_z)k \quad [14]\end{aligned}$$

where the coefficients of the principal diagonal are the moments of inertia about the x, y, z axes, while the other coefficients are the negatives of the products of inertia about pairs of respective axes.

It must be clearly understood that the moments and products of inertia I_x, I_{xy}, . . . have no relation to the moments of inertia I, J of the beam section which occur in β ($\beta = 1/EI$); they denote the moments of inertia of a mass distribution β per unit length of the beam center line. In the dynamical analog of the statical problem, this mass distribution is allowed to move as a rigid body so that the linear velocity v of each point is equal to M, and so as to possess a rotation represented by $w = F$.

If the axes are properly chosen, namely, if they are made to coincide with the principal axes of inertia, then the products of inertia will vanish and a great simplification results. While theoretically this can always be done, the determination of principal axes of inertia in general requires solving an equation of the third degree. However, in case of plane beams, one of the principal axes of inertia is normal to the plane in which the beam lies so that two products of inertia vanish immediately. The determination of the remaining principal axes now involves only the solution of an equation of the second degree or can be carried out by means of the familiar Mohr circle diagram in which the moment of inertia is plotted along the horizontal axis and the product of inertia along the vertical axis resulting in a circle for the point obtained by taking different sets of axes.

In calculating products and moments of inertia about any point, the calculation of products or moments of inertia can be sometimes simplified by recalling the following theorems: The moment of inertia about any line l is equal to the moment of inertia about a line through the center of gravity parallel to l plus the moment of inertia about l of the whole mass placed at the center of gravity. Similarly, the product of inertia of any mass distribution about two mutually perpendicular axes l_1, l_2 is equal to the sum of the product of inertia about axes parallel to l_1, l_2 and passing through the center of gravity plus the product of inertia about l_1, l_2 of the whole mass placed at the center of gravity.

If the section at P_1 is not held fast, then to the integral Equation [8] must be added the displacement

$$R_1 \times r_2$$

where R_1 is the vector rotation of the end P_1.

Examples

To illustrate this analogy we shall first consider a simple cantilever beam, as shown in Fig. 2, of length l along the positive

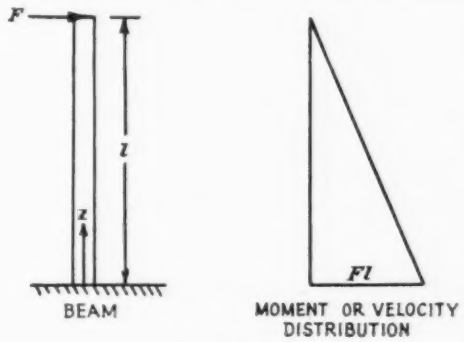

Fig. 2

z-axis with a built-in end P_1 at the origin and loaded at the free end P_2 with the force Fi. The moment distribution is given by

$$M = F(l - z)j$$

and corresponds to the velocity distribution due to a rotation of the cantilever bar about the free end with the rotation vector

$$w = Fi$$

The moment of momentum is simply

$$w_x I_x i = F I_x i$$

Since the radius of gyration of the beam segment about one end is $l/\sqrt{3}$

$$I_x = \beta l \frac{l^2}{3} = \frac{\beta l^3}{3}$$

and the displacement is

$$\beta F \frac{l^3}{3} i$$

The momentum of the moving beam is

$$\frac{Fl}{2} lj = \frac{Fl^2}{2} j$$

hence the angular displacement of the free end is

$$Fl^2/2$$

As another example consider the temperature stresses in a pipe bend forming one horizontal and two vertical sides of a square of length of side l, with built-in ends, as shown in Fig. 3. The

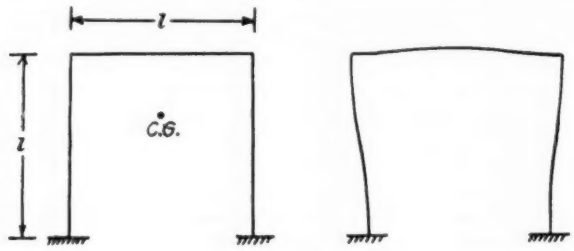

FIG. 3

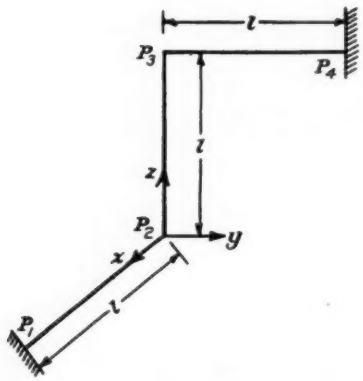

FIG. 4

problem is obviously equivalent to forcing the built-in ends against each other a distance

$$D = -kTl$$

where k is the temperature coefficient of linear expansion, while keeping them parallel. Now $\boldsymbol{D}$ is given, as well as $\int \boldsymbol{R} ds = 0$, and it is required to find the tractions and moments. Recalling the analogy, it will be noted that the total momentum of the motion vanishes; hence, the center of gravity of the beam must be stationary. Therefore, the tractions across any section, if reduced with respect to the center of gravity, are equivalent to a single force passing through it (and a vanishing couple); this force $\boldsymbol{F}$ obviously points in the direction of the horizontal member, which will be taken as that of the x-axis. Moreover, the vector distribution $\boldsymbol{R}ds$, having a zero resultant, will have a constant vector moment about any point of space; hence, in computing $\boldsymbol{D}$ one may obtain the moment of the $\boldsymbol{R}$ distribution, say about the center of gravity rather than about P_1. The center of gravity lies at a distance $l/3$ below the horizontal length. The moment of inertia about the rotation axis through the center of gravity is easily seen to be

$$I_x = (1/3)\beta l^3$$

Substituting in

$$D_x = F_x I_x$$

there results

$$F_x = -\frac{3kT}{\beta l^2}.$$

At the end points P_1, P_2 there is a traction of this amount as well as a bending moment of amount $(2/3)lF_x$ or $2kT/\beta l$. This is also the maximum bending moment.

In the foregoing, the twisting flexibility did not occur. We consider next a problem in temperature stresses of a three-dimensional pipe bend. Assume, as in Equation [3], the same flexibility in twisting as in bending. Let the pipe consist of three straight segments, as shown in Fig. 4, forming adjacent sides of a cube and joining adjacent pairs of the following points

$$P_1 = (l, 0, 0);\ P_2 = (0, 0, 0);\ P_3 = (0, 0, l);\ P_4 = (0, l, l)$$

The stresses developed by an expansion of T degrees are the same as those due to a displacement

$$\boldsymbol{D} = (kTl, -kTl, -kTl)$$

of the end P_4 relative to the end P_1, while at the same time keeping the sections at P_1, P_4 parallel to their original orientation. Again the total momentum $\int \boldsymbol{R} ds$ of the analogous motion vanishes, the center of gravity at $(l/6, l/6, l/2)$ is at rest, and this motion reduces to a rotation $\boldsymbol{F}$ about the center of gravity. The moments and products of inertia about axes through the center of gravity are readily found by first finding them for each segment relative to its center of gravity, then transferring relative to the common center of gravity. There results the following array for the inertia matrix

$$\frac{\beta l^3}{12}\begin{pmatrix} 10 & 1 & 3 \\ 1 & 10 & -3 \\ 3 & -3 & 6 \end{pmatrix}$$

leading to the equations

$$10F_x + F_y + 3F_z = \frac{12kT}{\beta l^2}$$

$$F_x + 10F_y - 3F_z = -\frac{12kT}{\beta l^2}$$

$$3F_x - 3F_y + 6F_z = -\frac{12kT}{\beta l^2}$$

for the force components F_x, F_y, F_z across the beam section. The solution of these equations is

$$F_x = \frac{3kT}{\beta l^2},\quad F_y = -\frac{3kT}{\beta l^2},\quad F_z = -\frac{5kT}{\beta l^2}$$

from which it is readily found that the maximum bending moment occurs at P_1 (or P_4) and is $10kT/3\beta l$. The maximum twisting moment has a value $kT/\beta l$ and exists at each cross section of the pipe from P_2 to P_3.

CASE OF UNEQUAL FLEXIBILITIES

For most engineering computations, the assumption of Equation [3] is satisfactory. If, however, β_1 is not equated to β_2 or β_3, a dynamical analogy can still be built up, though it is rather complex.

Equation [2] is now replaced by

$$\boldsymbol{R} = \beta_1 \boldsymbol{i}_1 m_1 + \beta_2 \boldsymbol{i}_2 m_2 + \beta_3 \boldsymbol{i}_3 m_3$$

where i_1 is the unit tangent vector and i_2, i_3 are unit vectors along the principal directions of the normal section; if

$$\beta_2 = \beta_3 = \beta, \beta_1 \neq \beta$$

then

$$R = \beta M + (\beta_1 - \beta)(M \cdot i_1) i_1$$

Interpreted as a velocity, R/β is seen to consist of two parts: Its previous value M which is like that of a rigid body motion, plus a component

$$\frac{\beta_1 - \beta}{\beta}(M \cdot i_1) i_1$$

along the tangent, corresponding to a sliding along the beam center line and proportional to the projection of M along it. Except for this change, the further analogy to the moment of momentum holds without modification. However, since the mass distribution does not move as a rigid body, the moment of momentum cannot be expressed merely in terms of moments and products of inertia. To the previous expressions for $\int R ds$ and D are to be added

$$(\beta_1 - \beta)\left[M_1 \cdot \int_{s_1}^{s_2} i_1 i_1 ds + F_1 \cdot \int_{s_1}^{s_2} (r \times i_1) i_1 ds \right]$$

$$(\beta_1 - \beta)\{ M_1 \cdot i_1 [i_1 \times (r_2 - r)] ds + F_1 \cdot \int (r \times i_1)(i_1 \times \overline{r_2 - r}) ds \}$$

respectively. The integrals and their integrands are dyadics depending on the geometry of the center line $r = r(s)$ only.

Beam Loaded Along Its Length

If in addition to terminal tractions there are also loads applied along the length of the beam, then the analogy to the simple dynamical problem breaks down further. Suppose, for instance, that there is a single load W applied somewhere at P' between two ends due to some constraining connection at P'. The resultant force F will then no longer be constant throughout the beam section but will change by an amount equal to W at P'. If the dynamical analogy is introduced, it would then be necessary to break up the mass distribution β into two parts at P', whereupon it will be found that the two parts will not move as a single rigid body but that each one will move as a separate rigid body; the velocity of the common end point of the two parts P' is the same, but the angular rotation of one part will differ from the other one.

In case there is a distributed load on the beam, it is advisable to drop the analogy completely and resort directly to the equations

$$\frac{dF}{ds} + W = 0$$

$$\frac{dM}{ds} + F \times i_1 = 0$$

which are analogous to the familiar beam equilibrium equations. The determination of the rotation vector per unit length R and of the displacement D in terms of R is carried out as before.

Comments on the Enthalpy of Saturated Steam From 0 to 100 C and Other Steam Properties

By FREDERICK G. KEYES,[1] CAMBRIDGE, MASS.

A FEW years ago the entire body of available thermodynamic data on water and steam was reviewed and correlated for the purpose of preparing steam tables (1).[2] At the time, precise experimental values of the thermal properties of saturated steam at temperatures below 50 C were not available. This gap, however, has recently been filled by the publication of an extraordinarily painstaking series of measurements by Osborne, Stimson, and Ginnings (2).

At the time referred to, it was known that the values of C_{p_0}, the specific heat of very low-pressure steam, would be slightly changed when more extensive spectroscopic data became available. This deficiency has now been supplied through the recent more extensive measurements on water vapor by Randall, Dennison, Ginsberg, and Weber (3). C. C. Stephenson and H. O. McMahon (4) have recently completed the laborious computations required to deduce the C_{p_0} magnitude from the extended recent spectroscopic data.

The distortion of the water molecule due to centrifugal forces was computed by Wilson (5) leading to a correction in the form $2\rho RT$, where $\rho = 2.04 \times 10^{-5}$, applicable to the earlier computations of C_{p_0} from the older spectroscopic data by A. R. Gordon (6) which had been used in formulating the steam tables. The new computations confirm the magnitude of the Wilson correction in a highly satisfactory way leading to a value of ρ in the mean equal to $\rho = 2.33 \times 10^{-5}$. This value is adopted and the following equation is an expression of our best knowledge of the specific heat of steam corresponding to zero pressure

$$C_{p_0}: \text{Int joule (1.0003)} = 1.4720 + 7.7716 \cdot 10^{-4} T + 47.8365 T^{-1} \quad \ldots\ldots\ldots [1]$$

This is the original correlation formula by Professor Keenan plus the correction term entering the coefficient of T, that is, $7.7716 \cdot 10^{-4}$ instead of the former $7.5566 \cdot 10^{-4}$.

The new formula produces a change in C_{p_0} at 100 C (1.8902, Equation [1], versus 1.8822) amounting to a part in 230. The values computed from Equation [1] are also confirmed by recent direct measurements (7) (1.8930, the mean at 100 C).

Collins and Keyes, besides reporting on directly measured C_{p_0} values, obtain values of $(\partial H/\partial p)$, from which the characteristic-state quantity for water vapor, B_0, from 38 to 135 C could be computed. These essentially confirm the older values extrapolated from higher temperatures. The new values, however, are somewhat larger but not enough to modify the computed properties of water vapor appreciably in the low temperature region. The saturation values of B or B_{sat} are given in the range 0 to 100 C by the equation

$$B_{sat}^{cc/g} = 1.89 - 6777.7\ T^{-1} - 1.0537 \cdot 10^{10}\ T^{-7} \ldots\ldots [2]$$

Used in the equation of state, $v_{sat} = R^* T/p_{sat} + B_{sat}$, the average deviation of the computed saturation volumes from those recently reported by Osborne, Stimson, and Ginnings is a part in 7700 (0 to 100 C, inclusive). The preferred vapor pressure equation (p_{sat}) for the same region based on the Reichsanstalt data is No. 11 of the Steam Research Program, Part IV (8).

The enthalpy equation for saturated vapor based on Equation [1] for C_{p_0} and B_{sat}, using the value of H_1 at 0 C given by Osborne, Stimson, and Ginnings to fix h_1, is

$$H_1^{\text{Int j}} = h_1 + 1.472\,(T - T_0) + 3.8858 \times 10^{-4}\,(T^2 - T_0^2) + 110.1476 \log_{10}(T/T_0) + [0.1915 - 1373.2 \times T^{-1} - 8.539 \cdot 10^{10} \times T^{-7}]p_{sat}^{**}$$

The value of h_1 using the latest enthalpy value of Osborne, Stimson, and Ginnings at 0 C (2500.3 Int j) (9) leads to $h_1 = 2500.78$ and the average deviation of the computed H_1 values at round 10 C from the recent values is a part in 5300. The deviation at 100 C is the largest amounting to a part in 2200. However, the values of the saturation enthalpy in the Steam Tables (Table 1) are also in agreement with the new values to a part in 1600 at 0 C; a part in 2200 at 50 C; and a part in 26,000 at 100 C, the reference point for establishing the steam tables constant of enthalpy.

An important contribution by Hans Eck (10) has also appeared recently on the saturation properties of water from 350 C to the critical temperature. Critical data for heavy water were also obtained.

The critical temperature of water is reported as 374.23. The value reported by Smith and Keyes is 374.11. This is better agreement than is usual in critical temperature measurements by different investigators. The critical pressures are: Eck, 218.258 atm; Smith and Keyes, 218.17—a part in 2500. The new critical volume is 3.0656 cc per gram compared with 3.14 cc of the Steam Tables. The critical magnitudes for heavy water are

$$t = 371.5 \text{ C};\ p_c = 214.387 \text{ atm};\ v_c = 2.74 \text{ cc per gram}$$

The critical-region saturation-liquid specific volumes reported by Eck are lower than those in the Steam Tables above 350, while the vapor saturation volumes are in tolerable agreement.

Measurement of Impact Strains by a Carbon-Strip Extensometer

By R. FANNING,[1] CAMBRIDGE, MASS., and W. V. BASSETT,[2] QUINCY, MASS.

This paper describes a method of experimentally ascertaining the actual stress-time curve in a mechanical part subjected to an impact blow. The apparatus consists of a resistance strain gage in conjunction with a high-speed recording oscillograph, the combination being sufficiently rapid in response to record strain variations occurring within a few microseconds. Consequently, the strains during impact are recorded with sufficient accuracy for detailed analysis.

Longitudinal strain waves in long bars striking end to end have been subjected to theoretical analysis and have served as a subject for testing of the apparatus. The theory is reviewed in this paper, and computed results based thereon are compared with experimental data. The agreement is shown to be satisfactory, the form being as predicted and the magnitude within a few per cent of the computed value.

The strain waves and reflections occurring in this simple case are surprisingly complex. An investigation of other impact problems by this method, such as the correlation of standard impact tests of materials, might well yield information of considerable value.

IN STARTING a program of impact research, the classical problem of the longitudinal strains in long bars was chosen for investigation because it was felt that it was a relatively simple type of impact and one which would serve as a means of checking the performance of the electric-resistance strain gage (Ess strip) which was under development at this time.

Strain-Gage Equipment

Strains were experimentally determined by use of a pickup which consists of a thin strip of elastic electricity-conducting material cemented to the strained surface. These strips change in resistance by about 1 per cent when strained 0.1 per cent (corresponding to a stress of 30,000 lb per sq in. in steel). Gages of this type have been developed at M.I.T. and at the Hamilton Standard Propeller Co. (1, 2, 3).[3] Those used in this investigation were the M.I.T. type, usually referred to as Ess (electrically strain-sensitive) strips.

The changes of resistance of the Ess strips due to strain were converted into voltage changes, amplified, and recorded by photographing cathode-ray-oscillograph tubes. The amplifier, oscillograph, and camera equipment used was that developed by Draper (4). The amplifiers when used in conjunction with the oscillograph tubes are flat in response from 1 or 2 cycles per sec to 40,000 cycles per sec, and are carefully corrected to give true reproduction of wave form. The recording was done on 35-mm motion-picture film driven at 400 in. per sec by a synchronous motor. Agfa ultraspeed panchromatic film was used with an f 1.5 lens and 2000 volts accelerating voltage on the cathode-ray tubes. Two independent channels are available in this equipment, so that two phenomena may be recorded simultaneously on the same film, thus allowing comparison of times.

Experimental Setup

The setup of the bars as well as the general scheme of electrical connections is shown in Fig. 1. Two bars were suspended horizontally by cords from a suitable framework so that they were free to swing in the direction of their length and to collide end to end. The bars were of alloy steel $1^1/_{16}$ in. in diameter and each was originally 6 ft long. Of the two ends which met in impact, one was always flat, the other a spherical surface of known radius. The bars were adjusted to be just in contact when hanging free. The impact was provided by drawing back one bar a known amount (10 in. in most cases) and allowing it to swing back by gravity. The radius of swing was 32 in. The bar was released by a synchronizing mechanism which at the proper time also engaged a clutch, causing the film to be driven through the recording apparatus. In Fig. 1, channel 1 is shown set up to record the time of contact of the bars, channel 2 to record strain at *A*, *B*, or *C*.

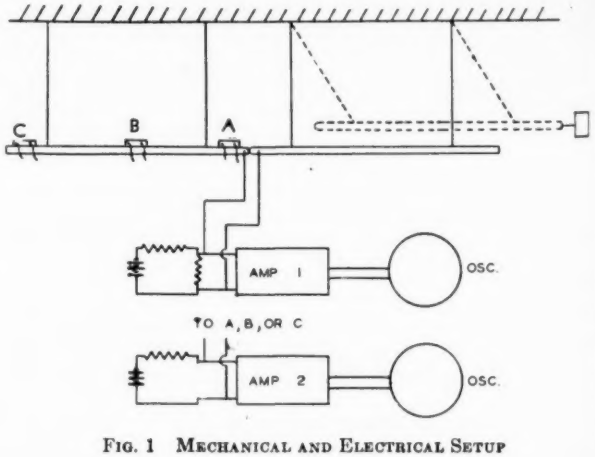

Fig. 1 Mechanical and Electrical Setup

Experimental Results

Fig. 2 is a composite print showing strain records taken at three different points on a bar 6 ft in length which was withdrawn $7^1/_4$ in. and allowed to strike a stationary 6-ft bar. An electrical contact record (*d*) is shown below the three strain records. Record (*a*) is that given by an Ess strip denoted as *A* located $5^5/_8$ in. from the striking end of the colliding bar, record (*b*) by a strip *B* at the center, and record (*c*) by a strip *C* $5^5/_8$ in. from the far end of the bar. The time scales for these prints coincide. The strain

[3] Numbers in parentheses refer to the Bibliography at the end of the paper.

Presented at the Annual Meeting, Philadelphia, Pa., December 4–8, 1939, of The American Society of Mechanical Engineers.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

scales are not exactly identical, but provide qualitative comparison of magnitude.

It is evident that after the bars have struck, a wave of compression proceeds at the speed of sound in steel, down the bar to the far end, after which a reflected wave of the opposite sign returns relieving the compression. Thus, shortly after collision a build-up of compressive strain is recorded by strip *A*. At an appropriate time, corresponding to the velocity of the sound wave in steel and the distance traversed, strips *B* and *C* also record this increase in strain. Since the wave form is one

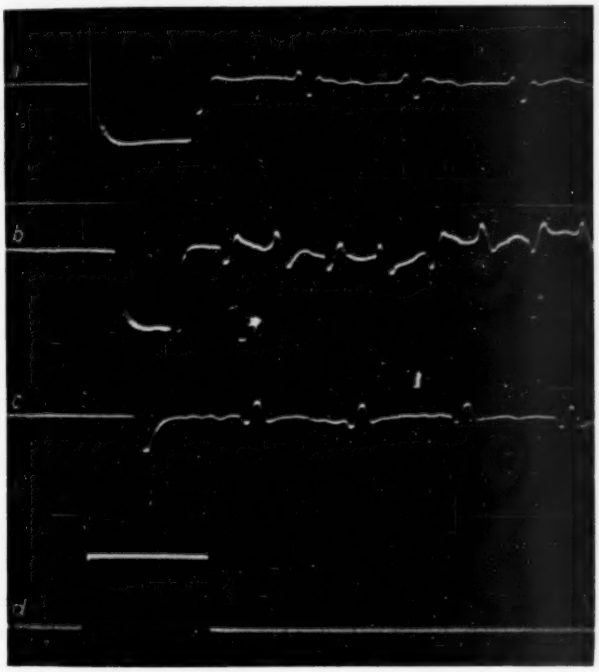

FIG. 2 LONGITUDINAL STRAINS IN LONG BARS

of pressure building up to a practically steady value, strain in the region through which the wave front has passed will maintain a constant level until the return of the reflected wave.

The reflected wave front of relief of compression reaches strips *C*, *B*, and *A* in that order. When the reflected wave reaches the near end of the bars, where they are in contact, and has reduced the pressure between them to zero, the bars separate and the impact is over. After this the waves of strain travel up and down the bars, reflecting at each end with change of sign. Knowing the record film speed, velocity of sound waves in steel (18,000 fps), and strip locations, the time of each event on the records has been checked and found to agree with the times predicted by theory.

At positions *A* and *B*, compression has reached the steady maximum value before arrival of the reflection, and remains at this value for an appreciable time. At point *C* this is not so; the toe of the reflection wave returns and cuts off the increase of strain before it has reached the maximum value.

Flexural vibration or bending of the bars due to eccentric impact was suspected in some of the records. By cementing strips diametrically opposite each other at the same section of a bar and connecting one strip to each amplifier channel, such bending vibrations were found to occur when the bars were not aligned with sufficient care.

COMPARISON OF EXPERIMENTAL RESULTS WITH THEORY

In order to determine whether the form of the strain-versus-time measurements obtained experimentally were correct, the problem was also subjected to analysis. Sears (6) treated this problem of impact of long bars with rounded ends. A calculation was therefore made by his method of the strains for a case which we had investigated experimentally. A summary of the method of calculation is given in the Appendix.

Fig. 3 shows the experimental and computed strains. The maximum ordinates were made to agree, to show most clearly the similarity of form of the curves. The actual calibration of the experimental gage gave a calibration constant about 10 per cent smaller than that used. This is within the possible error of the rather imperfect method of calibration which was used. Note that the strains considered here are those 5 5/8 in. in from the impacting end of the bar, not those at the very end. This had to be considered in an additional stage of the calculation, and gives rise to the bend in the curve at about 740 microseconds after the start of the impact. This is due, as noted on the curve, to the return of a reflected wave from the near end. The time marked on the curve as "contact ceases" is the calculated time for the

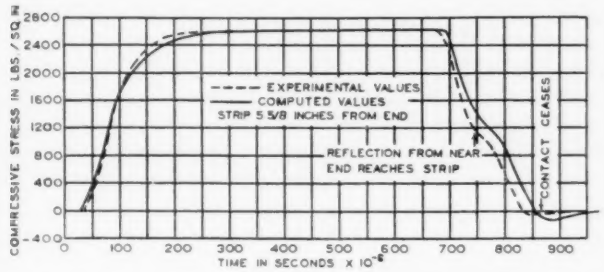

FIG. 3 CALCULATED AND EXPERIMENTAL STRESSES IN 6-FT BARS IN IMPACT

pressure at the end to fall to zero and so for the contact between the bars to cease. This would be the time given by such a record as (*d*) of Fig. 2. It is not exactly the time for a wave front to travel down and back through the bar. This would take about 715 microseconds. Since the wave front in these impacts is not an abrupt jump, it takes a considerable time for the returning wave of relief of compression to become of sufficient magnitude to cause the pressure at the point of contact to fall to zero. This difference between measured time of duration of impact and calculated time of sound travel through the bar has been the cause of considerable confusion, and Sears (6) must be given the credit for showing the cause of it. His paper gives many comparisons of measured times of duration of impact with those calculated from his theory, but he was unable at that time to measure the strains themselves. It is gratifying to be able to confirm his theory so directly.

OTHER EXPERIMENTAL RESULTS

Several other cases of impact were qualitatively examined. Fig. 4 shows the strains resulting from the impact of a 6-ft bar with a 1-ft bar. As before, waves travel to the end of each bar and back, but when the wave in the long bar has traveled 2 ft, the reflection in the 1-ft bar has returned to the contact, and soon after this pressure and consequently contact between the bars ceases. The result is a complete wave about 2 ft in length from toe to tail which is generated in the long bar. Fig. 4*b* shows the passage of this wave as recorded by a strip 6 in. from the contact end of the long bar. We see its initial passage, followed by its return after reflection from the far end, and again by its further reflection from the near end, and so on. Fig. 4*a* is a record of strain in the short bar, showing passage and return of the initial wave front. Analysis by simple wave theory pre-

Measurement of Impact Strains by a Carbon-Strip Extensometer

By R. FANNING,[1] CAMBRIDGE, MASS., AND W. V. BASSETT,[2] QUINCY, MASS.

This paper describes a method of experimentally ascertaining the actual stress-time curve in a mechanical part subjected to an impact blow. The apparatus consists of a resistance strain gage in conjunction with a high-speed recording oscillograph, the combination being sufficiently rapid in response to record strain variations occurring within a few microseconds. Consequently, the strains during impact are recorded with sufficient accuracy for detailed analysis.

Longitudinal strain waves in long bars striking end to end have been subjected to theoretical analysis and have served as a subject for testing of the apparatus. The theory is reviewed in this paper, and computed results based thereon are compared with experimental data. The agreement is shown to be satisfactory, the form being as predicted and the magnitude within a few per cent of the computed value.

The strain waves and reflections occurring in this simple case are surprisingly complex. An investigation of other impact problems by this method, such as the correlation of standard impact tests of materials, might well yield information of considerable value.

IN STARTING a program of impact research, the classical problem of the longitudinal strains in long bars was chosen for investigation because it was felt that it was a relatively simple type of impact and one which would serve as a means of checking the performance of the electric-resistance strain gage (Ess strip) which was under development at this time.

Strain-Gage Equipment

Strains were experimentally determined by use of a pickup which consists of a thin strip of elastic electricity-conducting material cemented to the strained surface. These strips change in resistance by about 1 per cent when strained 0.1 per cent (corresponding to a stress of 30,000 lb per sq in. in steel). Gages of this type have been developed at M.I.T. and at the Hamilton Standard Propeller Co. (1, 2, 3).[3] Those used in this investigation were the M.I.T. type, usually referred to as Ess (electrically strain-sensitive) strips.

The changes of resistance of the Ess strips due to strain were converted into voltage changes, amplified, and recorded by photographing cathode-ray-oscillograph tubes. The amplifier, oscillograph, and camera equipment used was that developed by Draper (4). The amplifiers when used in conjunction with the oscillograph tubes are flat in response from 1 or 2 cycles per sec to 40,000 cycles per sec, and are carefully corrected to give true reproduction of wave form. The recording was done on 35-mm motion-picture film driven at 400 in. per sec by a synchronous motor. Agfa ultraspeed panchromatic film was used with an f 1.5 lens and 2000 volts accelerating voltage on the cathode-ray tubes. Two independent channels are available in this equipment, so that two phenomena may be recorded simultaneously on the same film, thus allowing comparison of times.

Experimental Setup

The setup of the bars as well as the general scheme of electrical connections is shown in Fig. 1. Two bars were suspended horizontally by cords from a suitable framework so that they were free to swing in the direction of their length and to collide end to end. The bars were of alloy steel $1^1/_{16}$ in. in diameter and each was originally 6 ft long. Of the two ends which met in impact, one was always flat, the other a spherical surface of known radius. The bars were adjusted to be just in contact when hanging free. The impact was provided by drawing back one bar a known amount (10 in. in most cases) and allowing it to swing back by gravity. The radius of swing was 32 in. The bar was released by a synchronizing mechanism which at the proper time also engaged a clutch, causing the film to be driven through the recording apparatus. In Fig. 1, channel 1 is shown set up to record the time of contact of the bars, channel 2 to record strain at *A*, *B*, or *C*.

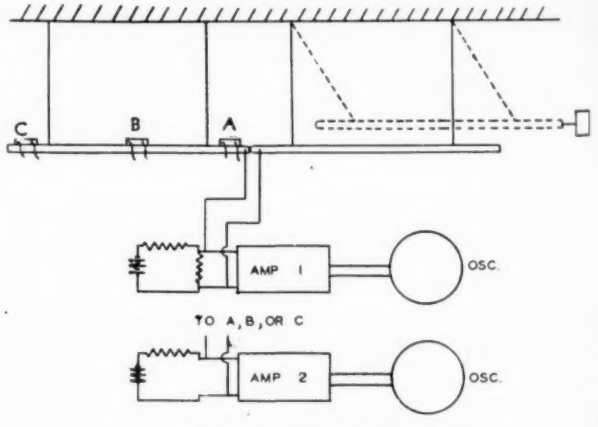

FIG. 1 MECHANICAL AND ELECTRICAL SETUP

Experimental Results

Fig. 2 is a composite print showing strain records taken at three different points on a bar 6 ft in length which was withdrawn $7^1/_4$ in. and allowed to strike a stationary 6-ft bar. An electrical contact record (*d*) is shown below the three strain records. Record (*a*) is that given by an Ess strip denoted as *A* located $5^5/_8$ in. from the striking end of the colliding bar, record (*b*) by a strip *B* at the center, and record (*c*) by a strip *C* $5^5/_8$ in. from the far end of the bar. The time scales for these prints coincide. The strain

Presented at the Annual Meeting, Philadelphia, Pa., December 4–8, 1939, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

scales are not exactly identical, but provide qualitative comparison of magnitude.

It is evident that after the bars have struck, a wave of compression proceeds at the speed of sound in steel, down the bar to the far end, after which a reflected wave of the opposite sign returns relieving the compression. Thus, shortly after collision a build-up of compressive strain is recorded by strip *A*. At an appropriate time, corresponding to the velocity of the sound wave in steel and the distance traversed, strips *B* and *C* also record this increase in strain. Since the wave form is one

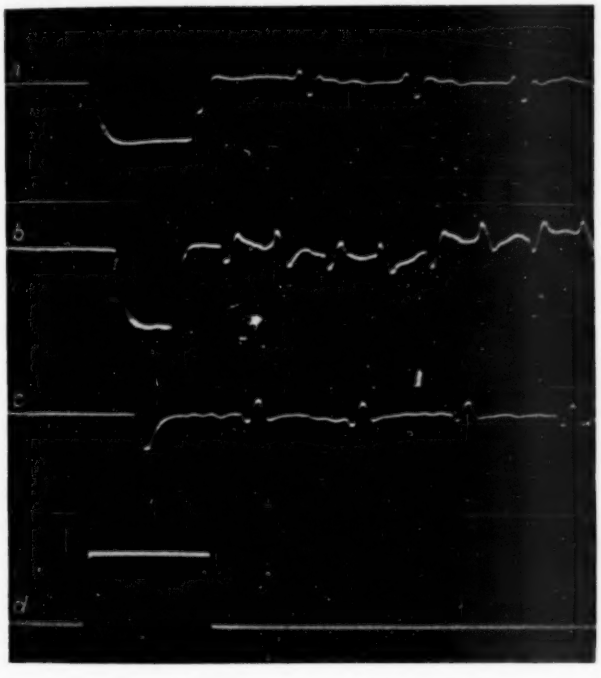

FIG. 2 LONGITUDINAL STRAINS IN LONG BARS

of pressure building up to a practically steady value, strain in the region through which the wave front has passed will maintain a constant level until the return of the reflected wave.

The reflected wave front of relief of compression reaches strips *C*, *B*, and *A* in that order. When the reflected wave reaches the near end of the bars, where they are in contact, and has reduced the pressure between them to zero, the bars separate and the impact is over. After this the waves of strain travel up and down the bars, reflecting at each end with change of sign. Knowing the record film speed, velocity of sound waves in steel (18,000 fps), and strip locations, the time of each event on the records has been checked and found to agree with the times predicted by theory.

At positions *A* and *B*, compression has reached the steady maximum value before arrival of the reflection, and remains at this value for an appreciable time. At point *C* this is not so; the toe of the reflection wave returns and cuts off the increase of strain before it has reached the maximum value.

Flexural vibration or bending of the bars due to eccentric impact was suspected in some of the records. By cementing strips diametrically opposite each other at the same section of a bar and connecting one strip to each amplifier channel, such bending vibrations were found to occur when the bars were not aligned with sufficient care.

COMPARISON OF EXPERIMENTAL RESULTS WITH THEORY

In order to determine whether the form of the strain-versus-time measurements obtained experimentally were correct, the problem was also subjected to analysis. Sears (6) treated this problem of impact of long bars with rounded ends. A calculation was therefore made by his method of the strains for a case which we had investigated experimentally. A summary of the method of calculation is given in the Appendix.

Fig. 3 shows the experimental and computed strains. The maximum ordinates were made to agree, to show most clearly the similarity of form of the curves. The actual calibration of the experimental gage gave a calibration constant about 10 per cent smaller than that used. This is within the possible error of the rather imperfect method of calibration which was used. Note that the strains considered here are those 5 5/8 in. in from the impacting end of the bar, not those at the very end. This had to be considered in an additional stage of the calculation, and gives rise to the bend in the curve at about 740 microseconds after the start of the impact. This is due, as noted on the curve, to the return of a reflected wave from the near end. The time marked on the curve as "contact ceases" is the calculated time for the

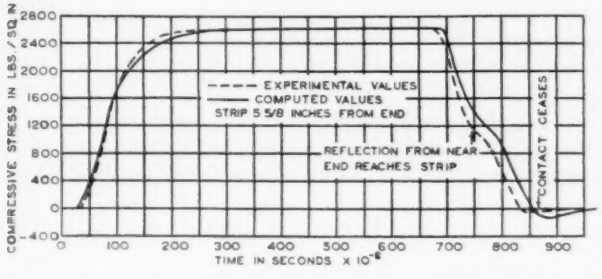

FIG. 3 CALCULATED AND EXPERIMENTAL STRESSES IN 6-FT BARS IN IMPACT

pressure at the end to fall to zero and so for the contact between the bars to cease. This would be the time given by such a record as (*d*) of Fig. 2. It is not exactly the time for a wave front to travel down and back through the bar. This would take about 715 microseconds. Since the wave front in these impacts is not an abrupt jump, it takes a considerable time for the returning wave of relief of compression to become of sufficient magnitude to cause the pressure at the point of contact to fall to zero. This difference between measured time of duration of impact and calculated time of sound travel through the bar has been the cause of considerable confusion, and Sears (6) must be given the credit for showing the cause of it. His paper gives many comparisons of measured times of duration of impact with those calculated from his theory, but he was unable at that time to measure the strains themselves. It is gratifying to be able to confirm his theory so directly.

OTHER EXPERIMENTAL RESULTS

Several other cases of impact were qualitatively examined. Fig. 4 shows the strains resulting from the impact of a 6-ft bar with a 1-ft bar. As before, waves travel to the end of each bar and back, but when the wave in the long bar has traveled 2 ft, the reflection in the 1-ft bar has returned to the contact, and soon after this pressure and consequently contact between the bars ceases. The result is a complete wave about 2 ft in length from toe to tail which is generated in the long bar. Fig. 4*b* shows the passage of this wave as recorded by a strip 6 in. from the contact end of the long bar. We see its initial passage, followed by its return after reflection from the far end, and again by its further reflection from the near end, and so on. Fig. 4*a* is a record of strain in the short bar, showing passage and return of the initial wave front. Analysis by simple wave theory pre-

dicts that the short bar would be free of vibration after separation, which this record shows to be essentially true.

Fig. 5 shows the strain record obtained by striking with another bar the end of a 5-ft bar, the other end of which has been cemented to a heavy iron support. The object of this setup was to obtain a fixed-ended bar. When a wave of strain encounters a free end, it has been seen to reflect as a strain of opposite sign. When a wave meets a fixed end, the result should be a reflection with the same sign, i.e., reflection should double the strain rather than reduce it to zero. The strip was attached near the free, impacting end of the bar. The initial passage of a compression wave was recorded as usual. The reflected wave shows an increase of strain as required by theory. It is not exactly doubled, since the end was not entirely fixed, and there was a momentary dip in the curve, caused probably by the fact that the bar was not firmly in contact with the large mass of iron at first.

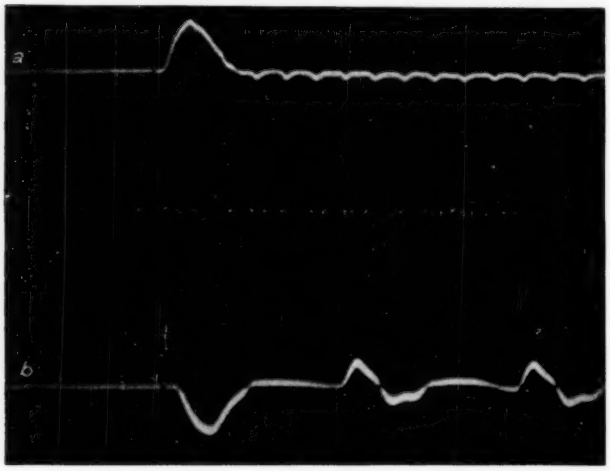

FIG. 4 IMPACT OF A 6-FT BAR AND A 1-FT BAR
[Strain at the near end of the (*a*) 1-ft bar and (*b*) 6-ft bar.]

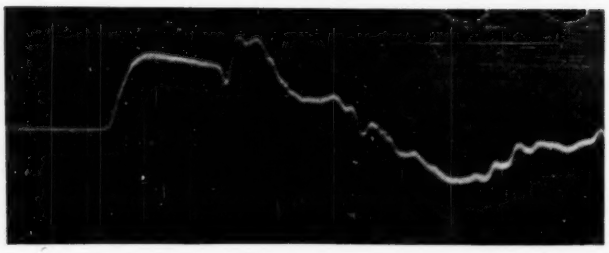

FIG. 5 REFLECTION OF STRAIN FROM A RELATIVELY FIXED END OF A LONG BAR

Records were obtained on bars which had holes of various sizes drilled through them. The object was to determine if a noticeable reflection was produced by such a discontinuity. No appreciable reflection of this sort was found on a single travel of a strain wave once through the bar, even when two holes at right angles were present which reduced the area of cross section of the bar at that point to a quarter of its original value. After the wave had traveled a number of times up and down the bar a slight cumulative effect due to the hole was observable, but still not important. Records were also made of the effect of interposing several layers of tape between the impacting ends of the bars. As was to be expected, the impact was "softened," i.e., the rate of build-up of strain was much lower.

Lateral impact of a compact mass against a beam has been studied recently by Arnold (8), using scratch-recording strain gages. We made a somewhat similar setup, using, however, a bar instead of a compact mass as the striking body, and a light rectangular bar as the struck beam. Fig. 6*a* is a record of strain near the striking end of the bar, and Fig. 6*b* is a record of contact between the bar and the beam. The first pulse on the strain record may be interpreted as due to the impact of the bar with the plug of beam material immediately under the contact end of the bar. This generates a compression pulse which traverses the length of the bar, much as in the case of a long bar striking a short one as shown in Fig. 4*b*. The reflection from the free end of the bar of this pulse momentarily breaks contact upon its return, which sets up further waves in the beam and the bar. These longitudinal vibrations of the bar are of high frequency, and give rise to the closely spaced makes and breaks of contact which are to be seen in Fig. 6. Actually this record shows a second series of contacts commencing about 0.011 sec after the last of the first series, but which is not shown in the portion of the record reproduced here. This longer break in contact, between series of closer spaced contacts, is considered to be due to flexural vibra-

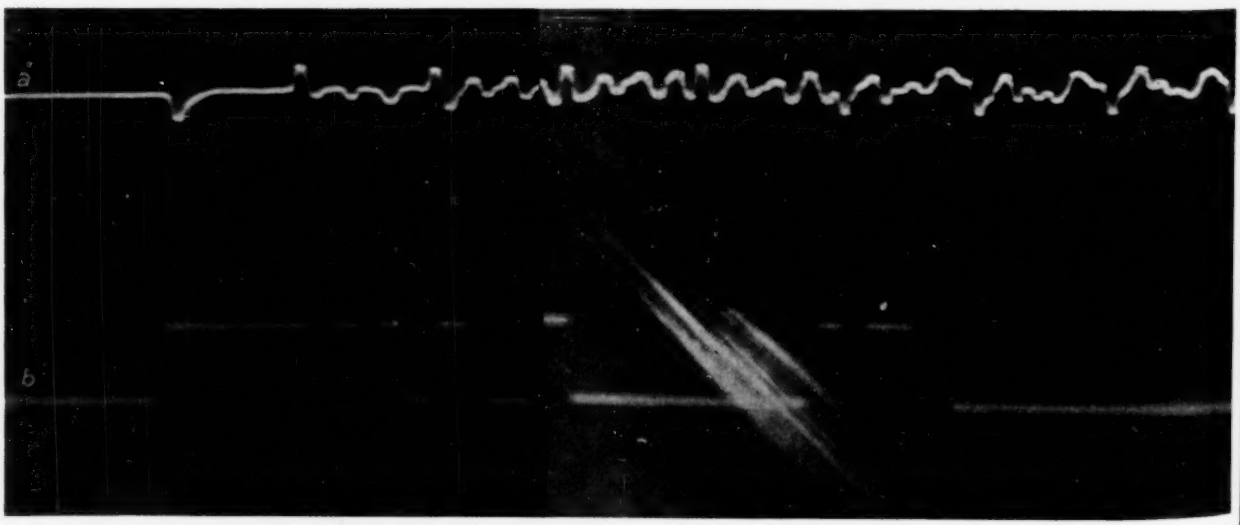

FIG. 6 STRAINS DUE TO THE LATERAL IMPACT OF A BAR AND A BEAM
[(*a*) Strain in striking the bar; (*b*) contact between the bar and beam.]

tions of the beam. It was breaks in contact of this sort which Arnold (8) found and which caused him to describe the phenomena as "multiple impact." In our case we have multiple impacts, each of which is itself a multiple impact due to longitudinal waves in the striking bar.

Conclusions

The longitudinal strains in long bars in impact have been recorded for a number of cases. The phenomena are found to be rather complicated. The case of two bars of equal length, each 6 ft, has been analyzed and the results of theory and experiment shown to agree. As a result of this check, considerable confidence is felt in the results obtained with the electrical-resistance strain gage for impact conditions. The strains obtained in the work reported in this paper were rather small, but further work has shown that the gages work successfully at much higher strains.

Acknowledgment

The experimental part of this work was done by the junior author as an S.M. thesis in mechanical engineering at M.I.T. We wish to acknowledge great indebtedness to Prof. A. V. de Forest in whose laboratory this work was done, for his encouragement and advice, as well as for the materials and equipment which he made available. Professor de Forest has reported this work in part (9).

Appendix

Method of Calculating Strains

The method used for calculating strains is that due to Sears (6). Actually stress is what is plotted in Fig. 3 but here clearly Hooke's law holds, and it was thought that stress figures were more familiar. Referring to Fig. 7, we note that all the force between the bars is transmitted through the small area of contact A. Thus, in the neighborhood of contact, the stress is essentially three-dimensional. However, we know by St. Venant's principle that the stress rapidly spreads out so that at a rather short distance from the contact region the stress, or the strain, is evenly distributed across the cross section.

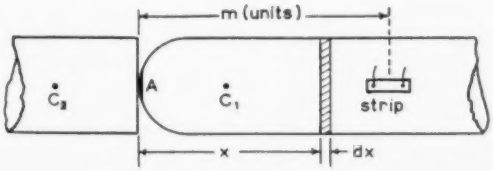

Fig. 7 Impacting Ends of Bars

For any element of the bar of length dx, the net force acting on it is

$$\Delta F = F - \left(F + \frac{\partial F}{\partial x}\,dx\right) = \frac{\partial F}{\partial x}\,dx$$

and now if ρ = density, g = acceleration of gravity, S = area of cross section, and u = displacement of element relative to axes fixed in space, then

$$\frac{\partial F}{\partial x}\,dx - \frac{\rho S}{g}\,\frac{\partial^2 u}{\partial t^2}\,dx = 0 \qquad [1]$$

but

$$F = SE\,\frac{\partial u}{\partial x} \qquad [2]$$

whence

$$E\,\frac{\partial^2 u}{\partial x^2} - \frac{\rho}{g}\,\frac{\partial^2 u}{\partial t^2} = 0$$

or

$$\frac{\partial^2 u}{\partial x^2} - \frac{1}{v^2}\,\frac{\partial^2 u}{\partial t^2} = 0 \qquad [3]$$

where $v = \sqrt{(Eg/\rho)}$ = velocity of sound. This equation holds in the interior of the bar. It has the well-known solution

$$u = f_1(t - x/v) + f_2(t + x/v) \qquad [4]$$

Now near the end of the bar, however, the strain is not governed by this one-dimensional-wave equation, but is essentially three-dimensional. Sears (6) shows that this region is small and that points C_1 and C_2 shown in Fig. 7 may be found for which, under static conditions, Hertz's law of deformation holds, i.e.

$$F = k\alpha^{3/2} \qquad [5]$$

where F = force between the bodies, k = a constant $= \dfrac{2E}{3(1-\sigma^2)}\left(\dfrac{r_1 r_2}{r_1 + r_2}\right)^{1/2}$, σ = Poisson's ratio, r_1 = radius of curvature of body 1 at region of contact, and r_2 = radius of curvature of body 2 at region of contact. Furthermore

$$AC_1 = AC_2 = c = a\,\sqrt{(3/2)} + a\pi EB\,\sqrt{(2/3)} \qquad [6]$$

where a = radius of the bar and

$$B = \left(\frac{6E + 5G}{3E + G} + 1\right)\frac{1}{4\pi G}$$

$$G = \frac{E}{2(1+\sigma)} = \text{modulus of rigidity}$$

Now since this region C_1C_2 is small we may neglect the effects of the finite time of propagation of strain through it for the moment and use Equation [5] for the impact case. The force thus found can then be considered to be acting at the very end of the bar, which is now considered as a one-dimensional system throughout for purposes of calculating wave travel. Now let β = displacement of C_1 relative to axes fixed in space, γ = displacement of C_2 relative to axes fixed in space, V_1 = original velocity of C_1, and V_2 = original velocity of C_2, all these being measured in the same direction in space, so $\alpha = \beta - \gamma$.

Now for our case, Equation [4] becomes

$$u = f_1(t - x/v) \qquad [7]$$

i.e., $f_2 = 0$, since it would correspond to a wave starting in the opposite direction in the bar.

Now from Equation [1]

$$\frac{\partial^2 u}{\partial t^2} - \frac{g}{\rho S}\,\frac{\partial F}{\partial x} = 0$$

but

$$F = SE\,\frac{\partial u}{\partial x} = -\frac{SE}{v}\,\frac{\partial u}{\partial t}$$

whence

$$\frac{\partial F}{\partial x} = -\frac{SE}{v}\,\frac{\partial}{\partial x}\left(\frac{\partial u}{\partial t}\right) = -\frac{1}{v}\,\frac{\partial}{\partial t}\left(SE\,\frac{\partial u}{\partial x}\right) = -\frac{1}{v}\,\frac{\partial F}{\partial t}$$

whence for the element at C_1, where $u = \beta$

$$\frac{\partial^2 \beta}{\partial t^2} + \frac{g}{\rho v S}\,\frac{\partial F}{\partial t} = 0 \qquad [8]$$

Integrating once

$$\frac{\partial \beta}{\partial t} + \frac{g}{\rho v S} F\left(t - \frac{x}{v}\right) = \text{const} = V_1$$

which we may write finally as

$$\dot{\beta} = V_1 - \frac{g}{\rho v} P\left(t - \frac{x}{v}\right) \quad \ldots\ldots\ldots\ldots\ldots [9]$$

and similarly

$$\dot{\gamma} = V_2 - \frac{g}{\rho v} P\left(t - \frac{x}{v}\right) \quad \ldots\ldots\ldots\ldots [10]$$

where $P = F/S$ = stress.

Now Equations [9] and [10] together with Equation [5] solve our problem. However, a solution in the form $P = p(t)$ is not possible in terms of known functions, so a step-by-step integration is necessary. Equations [9] and [10] hold until reflections return, whereupon further terms of the form $P_{t - \left(2l - \frac{x}{v}\right)}$ are to be added to the right-hand side of each equation.

Now integrating for a small time τ

$$\beta_t - \beta_{t-\tau} = V_1\tau - \frac{g}{\rho v}\int_{t-\tau}^{\tau} P\left(t - \frac{x}{v}\right) dt \ldots\ldots [11]$$

and now if $t = n\tau$, and we denote $\beta_{n\tau}$ as β_n, etc., and put

$$A_n = \frac{g}{\rho v}\int_{(n-1)\tau}^{n\tau} P\left(t - \frac{x}{v}\right) dt$$

$$= \frac{g}{2\rho v}(P_n + P_{n-1}) \text{ since } \tau \text{ is small}$$

$$= C(P_n + P_{n-1})$$

then

$$\beta_n = \beta_{n-1} + V_1\tau - A_{n-1} \ldots\ldots\ldots\ldots [12]$$

and similarly

$$\gamma_n = \gamma_{n-1} + V_2\tau - A_{n-1} \ldots\ldots\ldots\ldots [13]$$

and now we are given in our case V_1 = known velocity of striking bar at impact, $V_2 = 0$, $\beta_0 = \gamma_0 = 0$, $P_0 = P_{-1} = 0$, whence

$$A_0 = C(0) = 0$$

and from Equation [12]

$$\beta_1 = 0 + V_1\tau - 0 = V_1\tau$$

and from Equation [13]

$$\gamma_1 = 0$$

whence

$$\alpha_1 = (\beta_1 - \gamma_1) = V_1\tau$$

and $P_1 = k'\alpha_1^{3/2}$ which is now calculable, $k' = \frac{k}{S}$

we then have

$$A_1 = C(P_1 + P_0) = \frac{g}{2\rho v} P_1$$

and then

$$\beta_2 = \beta_1 + V_1\tau - A_1$$

$$\gamma_2 = \gamma_1 + 0 - A_1$$

of which all the terms on the right are known. Thus α_2 may be found, and then P_2 and so on.

When reflected waves return we have instead of Equation [9]

$$\beta_n = \beta_{n-1} + V_1\tau - A_{n-1} - A_{n-1-2l} \ldots\ldots\ldots\ldots \text{etc.}$$

This gives the stress at the end of the bar, or rather the stress which would exist in an imaginary bar at that point if the stress were distributed uniformly over the cross section right down to the end. However, our measured values were for a strip $5\frac{5}{8}$ in., or approximately 4 intervals of length c from the end. We calculate the stress there; thus:

Let P'_n = stress at time $n\tau$ at a point m units of length c in from the end. Then $P'_n = P_{n-m} - P_{n-(110-m)} + P_{n-(110+m)}$ since the length of the bar down and back is 110 units and P_{n-m} = stress at strip due to direct wave from near end, thus m units late; $P_{n-(110-m)}$ = stress at strip due to wave once reflected from far end (thus the negative sign); and $P_{n-(110+m)}$ = stress due to wave once reflected from far end, then once from near end (thus a positive sign).

For our case $m = 4$ and so

$$P_n' = P_{n-4} - P_{n-106} + P_{n-114}$$

as plotted in Fig. 3.

For this calculation the various constants had the following values: $a = 0.531$ in.; $c = 1.31$ in.; $r_1 = 0.531$ in.; $r_2 = \infty$; $v = 16{,}800$ fps $= 201{,}800$ in. per sec; $\tau = c/v = 6.491 \times 10^{-6}$ sec; $C = g/2\rho v = 2.211 \times 10^{-3}$; $V_1 = 34.75$ in. per sec; and $k' = k/S = 1.554 \times 10^7$.

Note that this value of c is not exactly that given by formula [6] but, as Sears (6) shows, its exact value is not of importance in the calculations, so that it is convenient to take it so that it is contained an integral number of times in the length of the bar. Thus, in our case this value of c makes the bar 55 units of this length long.

A Rational Representation of the Flow Performance of Reaction Steam-Turbine Blading

By ADOLF EGLI,[1] WINTERTHUR, SWITZERLAND

This paper gives a condensed method of representing flow performance of reaction-type turbine blading which is applicable to an extensive range of flow conditions including those widely different from the conditions of maximum efficiency. The method is of particular value in analyzing flow in by-pass blade groups of central-station turbines or of mixed-pressure or bleeder turbines. It is based on dimensional analysis and empirical data are presented in the condensed form suggested by the analysis.

THE blading of modern steam turbines is subjected to operation under very widely divergent flow conditions. Thus, the configuration of the flow in a by-pass blade group of a central-station turbine varies greatly with the load. In mixed-pressure turbines as well as in bleeder turbines complicated flow conditions occur due to externally regulated interstage pressures or externally imposed rates of steam flow. When the throttle valve of a high-pressure superposed turbine accidentally closes and the turbine continues to rotate at full speed as it is driven by the motorized generator, a certain amount of cooling steam must be admitted to prevent dangerous heating of the turbine. A similar situation exists in a marine propulsion turbine where special measures must be taken to avoid excessive heating of the ahead blading when operating astern.

The performance of turbine blading under all these conditions must be computed in advance be it as the basis for the greatly detailed turbine-performance guarantees customary today, be it to assure the safe mechanical operation of the power unit. It therefore has become necessary to develop methods of predicting the turbine flow characteristics under all possible modes of operation. While theoretical analysis of the flow in the blading yields much insight of a fundamental nature, a sufficiently accurate prediction of the performance of a steam turbine cannot be made by this procedure alone. The calculation of the behavior of the turbine is based on tests with an actual turbine.

The number of such tests, because of their cost, however, must be reduced to a minimum which, in turn, calls for the most rational methods of test analysis.

It is the purpose of this paper to show how, with the use of dimensional analysis, the most condensed method of representing turbine-flow performance is found. While this method of attack is applicable to any type or combination of types of turbine elements, the presentation in the paper has been restricted to the reaction type of turbine blading.

Presented at the Annual Meeting, Philadelphia, Pa., December 4–8, 1939, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until April 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

THE SINGLE-STAGE PROBLEM

Consider now a group of reaction-turbine blading. Rotating the spindle with a certain speed while maintaining a certain inlet pressure to the blading, a certain inlet temperature and a certain outlet pressure will, in general, set up a certain configuration of flow of the steam in the blading. A test, in fact, shows that the blading develops a certain definite power and consumes a certain definite amount of steam per unit of time.

In particular one stage out of the group, consisting of a stationary and a rotating blade row, is subjected to the initial pressure p, lb per sq ft; the initial temperature t, deg F; the pressure drop Δp, lb per sq ft; and the blade speed u, fps.

By changing the operating conditions of the blading group, we are able to vary at will any or all of the four stage quantities p, t, Δp, u. Representing furthermore the size of the blading by the characteristic length l, ft, we may consider the five quantities p, t, Δp, u, l the independent test variables. Giving each of them a certain value fixes a certain configuration of flow of the steam in the stage. The turbine designer is interested in certain effects of this flow, such as the work N, ft-lb per sec, delivered to the turbine shaft, the amount of fluid G, lb per sec, passing through the stage. In some instances he may want to know other characteristics of the flow, as, for instance, the temperature drop Δt, deg F, across the stage, and the mean relative efflux angle α of the flow from each blade row. The quantities N, G, Δt, α may then be considered the dependent variables of the reaction-stage problem. Of these dependent variables only two, the mass flow G and the power N, are more or less easily and accurately measurable in a turbine test. The others must be determined by mathematical analysis.

Presently with p, t, Δp, u, l, N, and G as the quantities usually measured in a turbine test, the test performance may be represented by the two functions

$$F_1(N;\ p;\ t;\ \Delta p;\ u;\ l) = 0 \quad \ldots\ldots\ldots\ldots [1a]$$

$$F_2(G;\ p;\ t;\ \Delta p;\ u;\ l) = 0 \quad \ldots\ldots\ldots\ldots [1b]$$

each of which contains six variables.

Plotting the test results in this manner, however, is exceedingly complicated. Allowing only ten values for each of the variables, it requires 2000 curve sheets to represent the two functions graphically. To obtain ten values for each independent test variable, a project of $10^6 = 100{,}000$ tests would have to be conducted.

Is it possible to simplify this situation without losing generality? The answer is obtained from dimensional considerations.

(*a*) *Dimensional Analysis of the Turbine Test.* Suppose we were able to calculate the function Equation [1*a*] analytically. The formula thus derived would, besides the six variables of Equation [1*a*], also contain variables representing the physical properties of the steam. The steam shall for the present purpose be represented by a gas with a constant-specific-heat ratio $k = c_p/c_v$ and a constant viscosity μ, lb sec ft^{-2}. The analytical expression

for the power output of the stage then would be of the general form

$$F(N;\ p;\ \rho;\ \Delta p;\ u;\ l;\ \mu;\ k) = 0 \ldots\ldots\ldots [2]$$

where we have, for convenience, replaced the temperature before the stage by the fluid mass density ρ, lb ft^{-4} sec^2, which is determined by p and t.

Equation [2] contains all the variables that are of importance in determining the power output N. To this equation we can directly apply the rules of dimensional analysis,[1] which are based on the observation that, applied to the present case, the phenomenon of the power developed by the turbine stage does not depend on the size of the units used to measure all the variables involved. It must therefore be possible to rearrange Equation [2] in such a manner that all variables are nondimensional ratios and thus independent of the measuring units.

It is shown in Table 1 that the dimensions of all eight variables involved can be expressed in terms of mass, length, and time, designated by M, L, and T, respectively.

TABLE 1 QUANTITIES INVOLVED IN THE REACTION-STAGE FLOW PROBLEM

Name	Symbol	Dimension expressed in products of powers of the fundamental units of mass, length, and time
Work done per unit time	N	ML^2T^{-3}
Reference length	l	L
Pressure before stage	p	$ML^{-1}T^{-2}$
Mass density before stage	ρ	ML^{-3}
Pressure drop across stage	Δp	$ML^{-1}T^{-2}$
Mean blade speed	u	LT^{-1}
Specific-heat ratio	k	1
Fluid viscosity	μ	$ML^{-1}T^{-1}$

Furthermore Buckingham's π theorem indicates that Equation [2] must be expressible in terms of $8 - 3 = 5$ nondimensional variables, say Ω; Δ; σ; Re; k. Thus, the new form of Equation [2] becomes

$$\Phi_1(\Omega;\ \Delta;\ \sigma;\ \mathrm{Re};\ k) = 0 \ldots\ldots\ldots [2a]$$

The five nondimensional variables, as found by the usual methods of dimensional analysis, result in

$$\Omega = N/l^2p\sqrt{(p/\rho)} = N/l^2p\sqrt{(gpv)} \text{ (mass flow)} \ldots [3a]$$

$$\Delta = \Delta p/p \text{ (pressure drop)} \ldots\ldots [3b]$$

$$\sigma = u/\sqrt{(p/\rho)} = u/\sqrt{(gpv)} \text{ (blade speed)} \ldots\ldots [3c]$$

$$\mathrm{Re} = \rho lu/\mu = lu/gv\mu \text{ (Reynolds' number)} \ldots [3d]$$

$$k = \text{(compressibility)} \ldots\ldots\ldots [3e]$$

with g = gravitational acceleration = 32.17 fps per sec.

A very similar analysis carried out for the mass flow Equation [1b] yields the function of nondimensional variables

$$\Phi_2(\Gamma;\ \Delta;\ \sigma;\ \mathrm{Re};\ k) = 0 \ldots\ldots\ldots [2b]$$

with the new variable representing the mass flow G

$$\Gamma = (G/g)/l^2p\sqrt{(p/\rho)} = Gv/l^2\sqrt{(gpv)} \ldots\ldots [3f]$$

Comparing now the nondimensional functions of Equations [2a] and [2b] with the original Equations [1a] and [1b], we observe that the number of variables has been reduced from six to five. This is the result of the simplifying assumption of constant and independent values μ and k. Actually of a real fluid, such as steam, μ and k are not constant and not independent. For practical reasons we are, however, forced to even further simplify the analysis.

Reaction blading usually operates with fluid velocities well below those of sound. Therefore, the compressibility of the fluid, which is represented by the value k, is generally of little importance in forming the flow through the blading. The variation of k will therefore be neglected. Furthermore, it is easily found that of the reaction stage of a given turbine the Reynolds number Re varies relatively little. Flow changes with Reynolds' number usually being slow, the effect of the variation of Re in the stage of a given turbine can be disregarded.

When comparing turbines of different sizes and widely different steam conditions, the effect of the viscosity is, however, of sufficient importance to be investigated separately.

All following considerations shall be assumed as referring to a range of conditions where the effect of a variation of Re is negligible. The test performance of the reaction stage, then, is represented by the two functions of three nondimensional variables each

$$\Omega = f(\Delta;\ \sigma);\quad \Gamma = f(\Delta;\ \sigma) \ldots\ldots\ldots [4]$$

which compare directly with the two functions expressed by Equations [1a] and [1b] of six variables each. Instead of 2000 curve sheets, we now need two to represent the functions graphically. Instead of 100,000 tests we need but 100 to cover ten values for each dependent variable.

Instead of the seven test variables p, t, Δp, u, l, N, and G we have now the four dimensionless quantities Δ, σ, Ω, and Γ defined in terms of the others by the Equations [3]. We call Δ, σ, Ω, Γ the fundamental test variables.

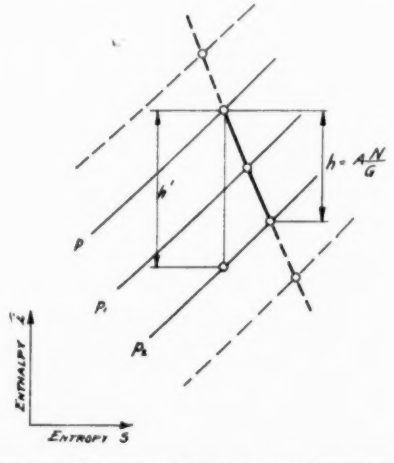

FIG. 2 ENTHALPY-ENTROPY DIAGRAM OF A SYMMETRIC REACTION STAGE

[1] "Dimensional Analysis," by P. W. Bridgman, Yale University Press, New Haven, Conn., 1931.

(*b*) *Characteristics Derived From the Fundamental Test Variables.* The configuration of the flow in the stage is now fixed as soon as certain values are given to two of the four fundamental test variables, say Δ and σ. From the turbine test we obtain directly only the two effects, power and mass flow, now represented by Equations [4]. An example each of a power and a flow characteristic is shown in Figs. 3 and 4 which are based on actual test results.

The turbine designer is interested, however, in a number of other stage characteristics. These must be obtained by analysis.

In the following derivations we will assume that the stage is "symmetric," that is, both blade rows have the same blade profile and the mean absolute velocity approaching the stage is the same in direction and magnitude as the mean absolute velocity leaving the stage. The two velocity triangles make the symmetric picture shown in Fig. 1; c representing velocities as seen by a stationary observer, and w representing velocities as seen by an observer moving with the speed u of the rotating blade row.

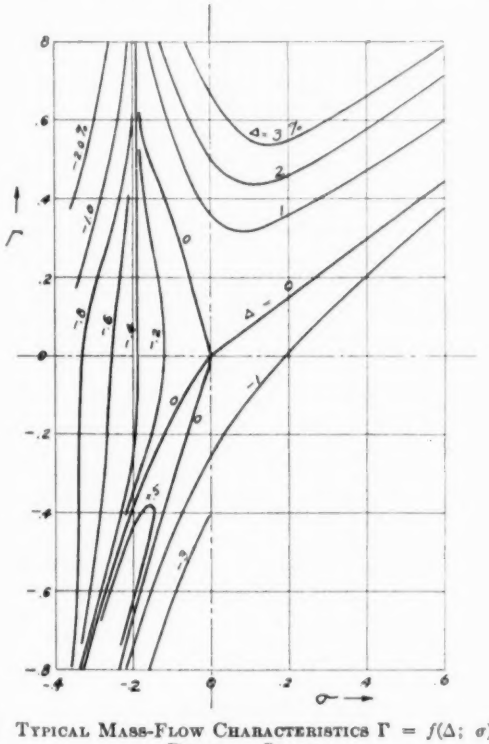

FIG. 3 TYPICAL MASS-FLOW CHARACTERISTICS $\Gamma = f(\Delta;\ \sigma)$ OF A REACTION STAGE

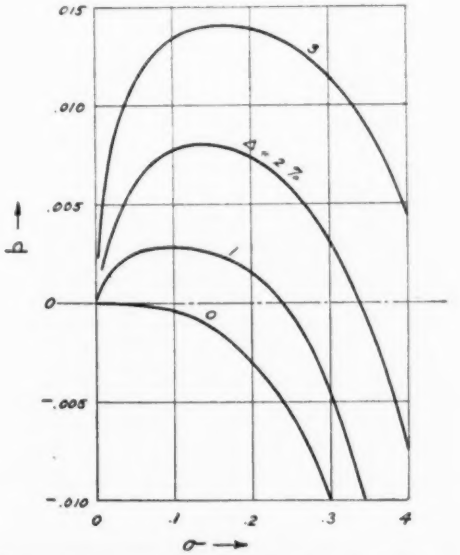

FIG. 4 TYPICAL WORK CHARACTERISTICS $\Omega = f(\Delta;\ \sigma)$ OF A REACTION STAGE

The energy equation for the stage

$$i - i_2 = cp(T - T_2) = AN/G \quad [5]$$

combined with Equations [3*a*] and [3*f*] yields the nondimensional expression τ for the stage temperature drop or stage enthalpy drop

$$\tau = \Omega/\Gamma = (i - i_2)/Apv = \frac{k}{k-1}(T - T_2)/T \quad [6]$$

where A = mechanical equivalent of heat = 778.3 ft-lb per Btu; i; i_2 = enthalpy before and after the stage, respectively, Btu per lb; and T; T_2 = absolute temperature before and after the stage, deg F.

The nondimensional temperature drop τ apparently is a function of Δ and σ; $\tau = f(\Delta;\ \sigma)$.

Denoting with α the relative angle of the flow leaving the row, the condition of continuity may be expressed as

$$G = z(ab/v)c_1 \sin\alpha \quad [7]$$

where a = blade pitch, ft; b = exit blade height of previous rotating blade row = exit blade height of stationary blade row, ft; and z = number of blades in the blade row.

The work done per second in the stage can be calculated by writing down the change of momentum in peripheral direction across the rotating blade row, thus

$$N = (G/g)u(2c_1 \cos\alpha - u) \quad [8]$$

Eliminating c_1 between Equations [7] and [8] and remembering the definitions of Ω, Γ, and σ, an equation for the leaving flow angle is obtained

$$\tan\alpha = (2l^2/zab)/(\sigma/\Gamma)(1 + \Omega/\Gamma\sigma^2) \quad [9]$$

We note that $\alpha = f(\Delta;\ \sigma)$.

Similarly we can derive the expressions for the velocity ratio

$$\nu = u/c_1 = 2\cos\alpha/(1 + \Omega/\Gamma\sigma^2) = f(\Delta;\ \sigma) \quad [10]$$

and the relative flow angle of approach

$$\tan\beta = \sin\alpha/(\cos\alpha - \nu) = f(\Delta;\ \sigma) \quad [11]$$

The blading efficiency which is, referring to the enthalpy-entropy diagram of Fig. 2, defined as

$$\eta = h/h' = AN/Gh' \quad [12]$$

can also be expressed in terms of the fundamental test variables. For the isentropic change of state across the stage we write if the pressure drop is small: heat added $\Delta q = 0 \cong \Delta i - Av\Delta p$, thus, $h' = \Delta i \cong Av\Delta p = Apv\Delta$. Eliminating h' and introducing the nondimensional test variables the blading efficiency becomes simply

$$\eta = \Omega/\Gamma\Delta = f(\Delta;\ \sigma) \quad [13]$$

If the pressure drop Δ is large, the approximation for Δi is not sufficient. The relation between h' and Δ is then found from the steam chart, or with an average value k from the general Bernoulli equation, and the expression for the efficiency becomes

$$\eta = \frac{Apv}{h'}\frac{\Omega}{\Gamma} = \frac{k-1}{k}\,\frac{\Omega/\Gamma}{1-(1-\Delta)^{(k-1)/k}} = (\Omega/\Gamma\Delta)\Big/\left(1 + \frac{\Delta}{2k} + \frac{k+1}{6k^2}\Delta^2 + \ldots\right) \quad [13a]$$

The isentropic velocity ratio $\nu' = u/c'$ often used in turbine calculations with $Ac'^2/2g = h'/2 \cong Av\Delta p/2$ becomes

$$\nu' = \sigma/\sqrt{\Delta} = f(\Delta;\ \sigma) \quad \ldots\ldots\ldots\ldots\ldots\ldots [14]$$

In line with customary procedure in aerodynamics the Mach number $M_a = c'/c_a$, where $c_a = \sqrt{g\,k\,pv}$ = acoustic velocity,

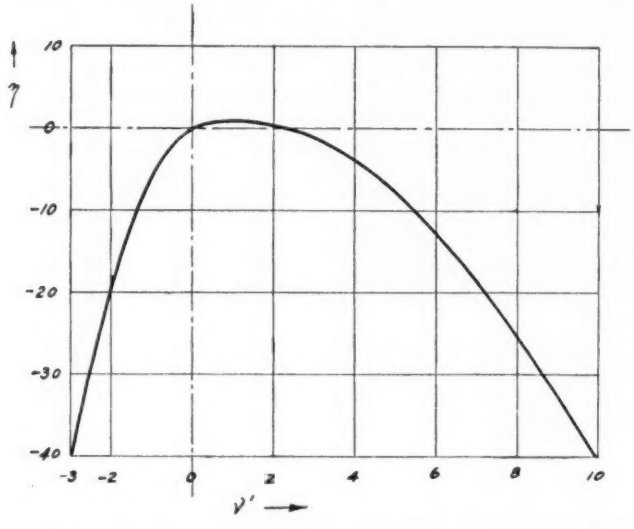

FIG. 5 TYPICAL EFFICIENCY CURVE $\eta = f(\nu')$ OF A REACTION STAGE

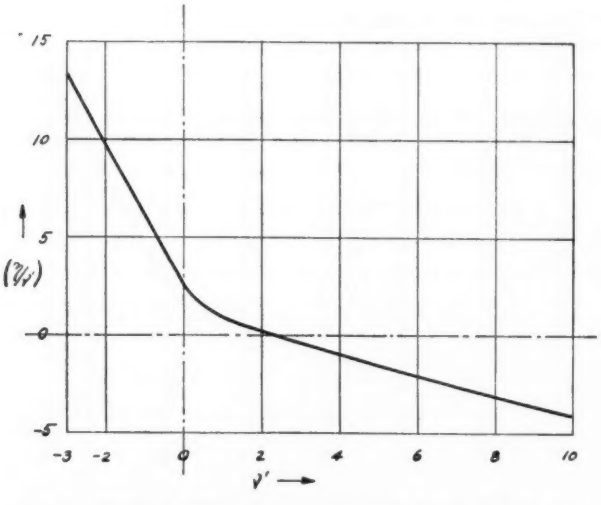

FIG. 6 TYPICAL TORQUE CHARACTERISTIC $(\eta/\nu') = f(\nu')$ OF A REACTION STAGE

is sometimes used as index of the importance of the compressibility of the fluid. It is easily found that M_a is related with Δ through the equation $M_a^2 \cong \Delta/k$. Also Δ is therefore an index of the effect of the compressibility of the fluid.

Summing up the results of our analysis, the flow performance of the reaction stage is described by a series of nondimensional functions; written symbolically

Work done	$\Omega = f(\Delta;\ \sigma)$	
Mass flow	$\Gamma = f(\Delta;\ \sigma)$	.....(4)
Temperature drop	$\tau = f(\Delta;\ \sigma)$	.....(6)
Leaving flow angle	$\alpha = f(\Delta;\ \sigma)$	.....(9)
Approach flow angle	$\beta = f(\Delta;\ \sigma)$	.....(11)
Velocity ratio	$\nu = f(\Delta;\ \sigma)$	.....(10)
Isentropic velocity ratio	$\nu' = f(\Delta;\ \sigma)$	.....(14)
Blading efficiency	$\eta = f(\Delta;\ \sigma)$	.....(13)

It sometimes proves convenient to combine two or more of

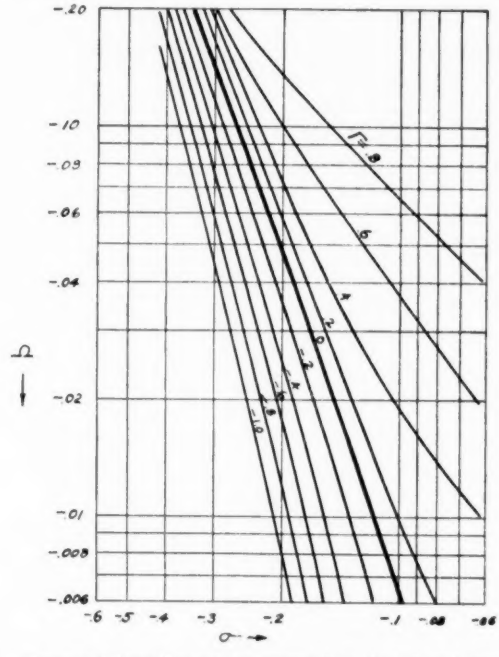

FIG. 7 TYPICAL WORK CHARACTERISTICS $\Omega = f(\sigma;\ \Gamma)$ OF A REACTION STAGE OPERATING IN ASTERN ROTATION

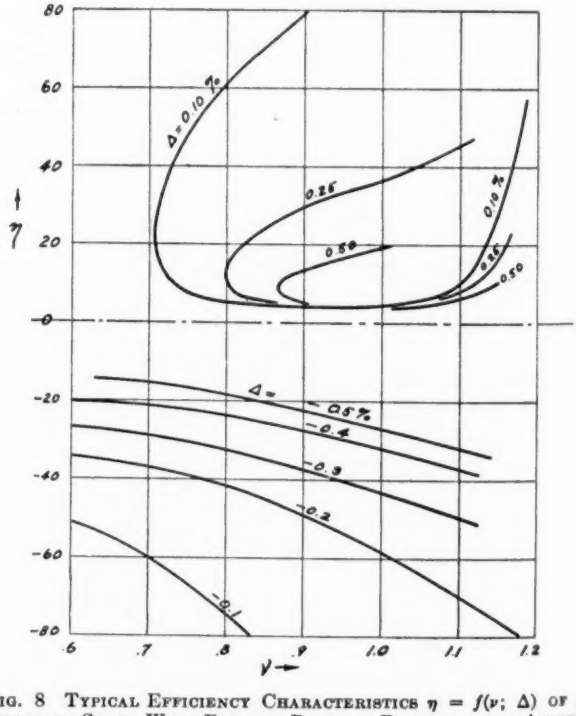

FIG. 8 TYPICAL EFFICIENCY CHARACTERISTICS $\eta = f(\nu;\ \Delta)$ OF A REACTION STAGE WITH FLOW IN REVERSE DIRECTION AND ASTERN ROTATION

these functions and thereby rearrange the variables. Thus, by eliminating σ between Equations [13] and [14] we obtain

$$\eta = f(\nu';\ \Delta) \quad [15]$$

In the normal operating range of reaction blading the influence of Δ on the efficiency has been found negligible. Therefore, $\eta = f(\nu')$ is the type of function usually applied in efficiency calculations, and for which Fig. 5, obtained from tests, is an example. In Fig. 6 the ratio (η/ν') is plotted against ν'; the former, as is easily verified, represents the torque transmitted to the turbine shaft.

Another example of rearranged variables is shown in Fig. 7 showing the power which is necessary to drive a reaction stage in reversed rotation as found from tests.

The test results represented in Fig. 8 show that in the efficiency function $\eta = f(\nu;\ \Delta)$, the influence of Δ is not always negligible.

The Multistage Problem

It is usually not possible to measure the output N of a single stage which is part of a group of stages. The characteristics of the single stage must be calculated by mathematical analysis from the measurements taken in a multistage test.

The single-stage characteristics thus obtained are then the basis for predicting the performance of other blade groups which may be portions of particular turbines.

Both these problems are fundamentally solved if the relationship between the characteristics of a single stage and a group of stages is known. This relationship is obtained in a straightforward manner if we start out with the single-stage characteristics. The details of this analysis are not within the scope of this paper.

Acknowledgment

The author wishes to acknowledge the conscientious work of C. A. Meyer of the Westinghouse Electric and Manufacturing Company in South Philadelphia, who analyzed the turbine tests. The author is grateful to the Westinghouse Electric and Manufacturing Company for permission to publish the results of the tests carried out in their South Philadelphia Works.

Design Data

It is important that the data contained in technical papers be made readily available to designing engineers. In order to satisfy these needs of industry, this section of the JOURNAL will include a concise presentation of data and information drawn chiefly from papers previously published by the Applied Mechanics Division of The American Society of Mechanical Engineers.

The first series dealt with the subject "Strength of Materials" and the present series will cover the subject "Vibration." The data have been prepared by a subcommittee of the Applied Mechanics Division (J. Ormondroyd, chairman), under the general guidance of S. Timoshenko.

The third article, which follows, is by J. Ormondroyd. This considers systems with one degree of freedom.

Vibration Problems

PART III—SYSTEMS WITH ONE DEGREE OF FREEDOM

BY J. ORMONDROYD,[1] ANN ARBOR, MICH.

THE lowest natural frequency of machines and structures is of particular interest to engineers for several reasons. In free vibrations, which occur after structures are distorted from their equilibrium positions by transient forces, it is the lowest-frequency natural vibration which usually has the largest amplitude and which persists in motion the longest. Therefore it is usually the motion at this natural frequency which is the easiest to detect. When periodic forces act on the structure the frequencies of these forces are more likely to coincide with the lowest natural frequency than with the higher modes, since the disturbing frequencies are more often of low frequency. Again a periodic force can act almost anywhere on the structure and excite the lowest mode of vibratory motion. For the higher frequency modes of natural vibration there are locations in the structure (nodes) at which the forces can act without exciting any response. The amplitude of motion at resonance with the lowest mode of motion is usually much larger than the amplitudes of the higher modes of motion, since both velocity and stress damping are generally lower in this mode than in the higher modes. All these possibilities make the lowest natural frequency of great practical importance in many engineering structures. The things of particular interest are the natural frequency itself and the possible amplitude at resonance if resonance occurs. Knowledge of the natural frequency coupled with information on the possible disturbing-force frequencies indicates if resonance is likely to occur while the structure is in use. The resonance amplitudes of the various parts of the structure indicate if the resonance condition may lead to trouble.

The practical problem presented in calculating the motion of any system in its lowest frequency form is to replace the actual system by an equivalent simple system of one degree of freedom. For linear vibrations the equivalent system has the form shown in Fig. 1. From the actual details of the system the equivalent values of k, m, and damping constants must be calculated. The equivalent spring constant k and the equivalent mass m are usually easy to calculate. The damping properties are more difficult to evaluate and frequently they are obtainable only by free-vibration experiments after the structure has been built. The lowest-frequency vibration of a rotor simply supported on two bearings is a problem which frequently confronts designers. This simple case is represented in Fig. 2. For many practical cases the weight of the shaft can be ignored, in which case the value of m to be used in the equivalent system, shown in Fig. 1, is W/g lb sec²/in. The value of the equivalent k is found by calculating the deflection under the load P (any convenient load for calculation purposes) on the beam, abstracted from Fig. 2 and shown in Fig. 3, assuming that the rotor is rigid. The deflection Δ, under the test load P, can be calculated by the energy method or graphical method which were referred to previously.[2] Having found Δ in inches under the load P

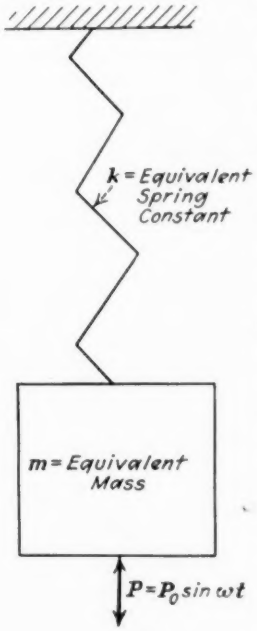

FIG. 1

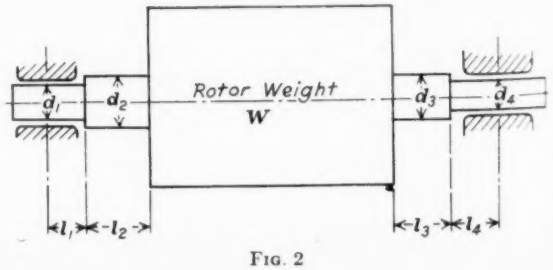

FIG. 2

[1] Professor of Engineering Mechanics, University of Michigan. Mem. A.S.M.E.

NOTE: In part II of these design data on vibration problems, JOURNAL OF APPLIED MECHANICS, Trans. A.S.M.E., vol. 61, September, 1939, the formula for the torsional-spring constant of a truncated cone, given at the top of the right-hand column on p. A-129, should read

$$\frac{3G}{32l}\,\frac{\pi(d_2 - d_1)\,d_1^3 d_2^3}{d_2^3 - d_1^3}$$

[2] "Vibration Problems—Part II," by J. Ormondroyd, JOURNAL OF APPLIED MECHANICS, Trans. A.S.M.E., vol. 61, September, 1939, p. A-127.

given in pounds, the equivalent spring constant $k = P/\Delta$ lb per in.

For torsional vibration the simple equivalent system is shown in Fig. 4 in which the equivalent torsional-spring constant k and the equivalent moment of inertia I are calculated from the actual details. As an example of a system which looks nothing like the one shown in Fig. 4, but which can be reduced to one similar to it for calculation purposes, we might take the suspended sign shown in Fig. 5. The lowest-frequency oscillation of this sign in the vertical plane can occur only by rotations about the pivoted suspension at A. The equivalent moment of inertia I about the axis perpendicular to the plane of the figure through A, including the sign and the horizontal bar AB, is

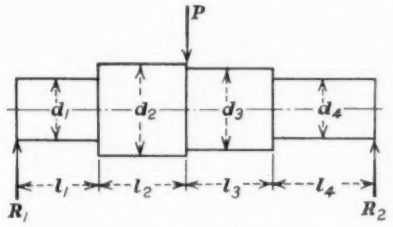

Fig. 3

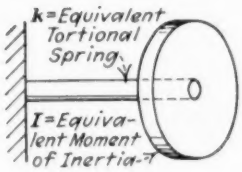

Fig. 4

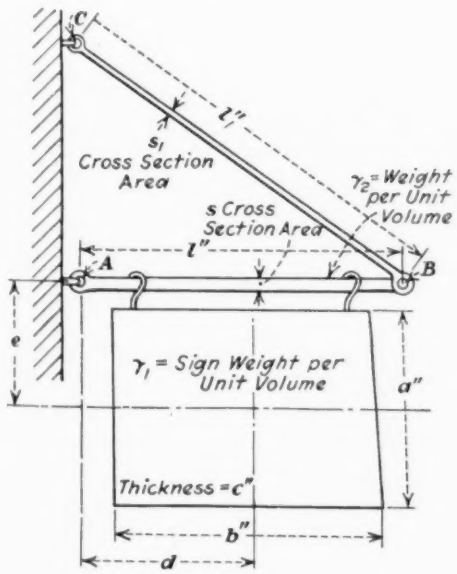

Fig. 5

$$I = \frac{abc\gamma_1}{g}\left(\frac{a^2 + b^2}{12} + d^2 + e^2\right) + \frac{sl\gamma_2}{g}\frac{l^2}{3} \quad \ldots\ldots [1]$$

The equivalent torsional-spring constant about the same center A (including only the elastic effect of the diagonal suspension rod BC) is

$$k = \frac{Es_1l^2}{l_1}\sin^2\theta \quad \ldots\ldots [2]$$

where θ is the angle between the suspension rod and the horizontal bar. In this case again the damping effects would be hard to predict by calculations, but easy to measure by free-vibration tests on the completed construction.

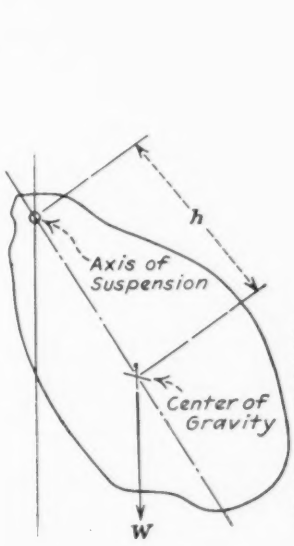

Fig. 6

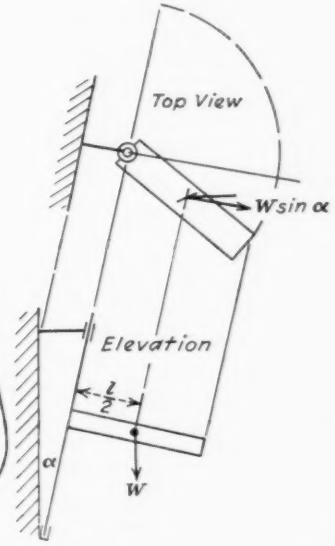

Fig. 7

Fig. 6 shows the simple system to which pendulous structures can be reduced. Here the details of an actual system, such as shown in Fig. 7, provide the data from which the weight, moment of inertia about the suspension point, distance between the center of gravity and the suspension point, and damping characteristics are calculated. In Fig. 7

$$I = \frac{W}{g}\frac{l^2}{3} \quad \ldots\ldots [3]$$

The moment restoring the bar AB to its lowest position is

$$M = Wl\frac{\sin\alpha}{2}\phi \quad \ldots\ldots [4]$$

if the amplitude of oscillation is small.

In the vibration of the system shown in Fig. 1 under the action of P, a simple harmonic periodic force in the direction of its possible motion, the forces acting on the mass m can be recorded in proper relationship by using Newton's second law

$$m\frac{d^2x}{dt^2} = -c\frac{dx}{dt} - kx + P_0\sin\omega t \quad \ldots\ldots [5]$$

x is measured from the position of static equilibrium and the damping from every source is lumped into one equivalent viscous damping. The complete solution of this differential equation is

$$x = e^{-qt}\left[A\cos\sqrt{(p^2 - q^2)}t + B\sin\sqrt{(p^2 - q^2)}t\right] + \frac{P_0}{k}\frac{\sin\left[\omega t - \tan^{-1}\frac{2q}{p}\frac{\omega/p}{1-(\omega^2/p^2)}\right]}{\sqrt{\left[\frac{4q^2}{p^2}\frac{\omega^2}{p^2} + \left(1 - \frac{\omega^2}{p^2}\right)^2\right]}} \quad \ldots\ldots [6]$$

If at $t = 0$, $x = x_0$ and $\dot{x} = \dot{x}_0$, the corresponding values of A and B (the constants of integration) give

$$x = e^{-qt}\left\{\left[x_0 + \frac{P_0}{k}\frac{(2q/p)\,\omega/p}{\frac{4q^2}{p^2}\frac{\omega^2}{p^2} + \left(1-\frac{\omega^2}{p^2}\right)^2}\right]\cos\sqrt{(p^2-q^2)}t + \frac{1}{\sqrt{(p^2-q^2)}}\left[\dot{x}_0 + qx_0 + \left(1-2\frac{1-(\omega^2/p^2)}{4q^2/p^2}\right)q\frac{P_0}{k} \times \frac{(2q/p)\,\omega/p}{\frac{4q^2}{p^2}\frac{\omega^2}{p^2} + \left(1-\frac{\omega^2}{p^2}\right)^2}\right]\sin\sqrt{(p^2-q^2)}t\right\} + \frac{P_0}{k}\frac{1}{\sqrt{\left[\frac{4q^2}{p^2}\frac{\omega^2}{p^2} + \left(1-\frac{\omega^2}{p^2}\right)^2\right]}}\sin\left[\omega t - \tan^{-1}\frac{2q}{p}\frac{\omega/p}{1-(\omega^2/p^2)}\right] \quad \ldots [7]$$

The first term is known as the transient-motion term and dies away in time. Motion represented by this term is brought into existence at any time if the conditions and circumstances of the system change. The second term is the steady-state solution and the motion it represents exists as long as the disturbing force acts.

In Equation [7] $p^2 = k/m$, $q^2 = c^2/4m^2$, and P_0/k is known as the static deflection of the system under a steady load of P_0. Equation [7] contains the solution of motion for free vibrations if P_0 is given the value zero. It then reduces to

$$x = x_0 e^{-qt}\left[\cos\sqrt{(p^2-q^2)}t + \frac{(\dot{x}_0/x_0)+q}{\sqrt{p^2-q^2}}\sin\sqrt{(p^2-q^2)}t\right] \quad \ldots [8]$$

If two phases of the free vibration at time t and time $t+T$ [where $T = 2\pi/\sqrt{(p^2-q^2)}$] are compared, the ratios of the instantaneous excursions of the body from the zero position at these two times will be

$$\frac{x_t}{x_{t+T}} = e^{2\pi(q/\sqrt{(p^2-q^2)}} \quad \ldots [9]$$

The logarithmic decrement of the system is

$$\log_e\frac{x_t}{x_{t+T}} = 2\pi\frac{q}{\sqrt{(p^2-q^2)}} \quad \ldots [10]$$

The natural frequency of the system is $(1/2\pi)\sqrt{(p^2-q^2)}$. When $p = q$, the system is said to have critical damping. Under critical-damping conditions the natural frequency is zero, that is, the disturbed system returns to its position of static equilibrium by a motion which never reverses direction.

Now, $1/q$ is called the "time constant" of the system—it represents the time which is taken for the amplitude of motion of the disturbed system to die down to $1/e$ times the first maximum value which occurs.

In the steady-state motion when $(\omega^2/p^2) = 1-(2q^2/p^2)$, the amplitude of motion has its maximum value $\frac{P_0}{k}\frac{p}{2q}\frac{1}{\sqrt{[1-(q^2/p^2)]}}$. For small damping the maximum amplitude occurs very near to $\omega^2/p^2 = 1$ and has the magnitude $\frac{P_0}{k}\frac{p}{2q}$.

Calculation of the Lowest Natural Frequency

For small values of damping the natural frequency is close to $p/2\pi = (1/2\pi)\sqrt{(k/m)}$. Since most actual structures have very small damping, this last expression is very useful for approximate calculations of natural frequencies.

For the system shown in Fig. 1

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}} = \frac{1}{2\pi}\sqrt{\frac{g}{\Delta}} \quad \ldots [11]$$

where k = equivalent linear spring constant, m = equivalent mass, and Δ = static deflection of system under load mg.

In Fig. 4

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{I}} = \frac{1}{2\pi}\sqrt{\frac{g}{\Delta'}} \quad \ldots [12]$$

where k = equivalent torsional-spring constant, I = equivalent moment of inertia, and Δ' = static deflection at end of a horizontal radius of gyration considering the whole weight concentrated there.

In Fig. 6

$$f = \frac{1}{2\pi}\sqrt{\left[\frac{g}{h+(k^2/h)}\right]} = \frac{1}{2\pi}\sqrt{\frac{g}{l'}} \quad \ldots [13]$$

where h = distance between axis of suspension and center of gravity of pendulous mass; k = radius of gyration for moment of inertia about axis parallel to suspension axis and passing through center of gravity; and l' is the length of the equivalent mathematical pendulum.

Rayleigh's Approximate Method of Calculating the Lowest Natural Frequencies of Mechanical Systems

In any freely vibrating system of bodies the sum of the various types of mechanical energies is always constant. Neglecting friction losses

$$U + T = \text{const} \quad \ldots [14]$$

where U = potential energy, and T = kinetic energy. When the vibrating system has reached its maximum excursion from the position of static equilibrium, the vibratory velocity is zero and the entire local energy of the system is all potential energy

$$U_{max} = \text{const} \quad \ldots [15]$$

When the system is moving through the position of static equilibrium the entire local energy is all kinetic. Here

$$T_{max} = \text{const} \quad \ldots [16]$$

This indicates that $U_{max} = T_{max}$ $\ldots [17]$

The quantitative values of U_{max} and T_{max} can be calculated for any vibrating system if the relative amplitudes of motion of the various masses in the system are known. Equation [17] gives a means of calculating p^2 for the system.

In elastic systems this principle can be used in two separate, but closely related, ways if the "normal elastic" curve of the system is known. The "normal elastic" curve of any system in the lowest frequency mode of vibratory motion is a space diagram of the system which shows the relative amplitudes of the various masses of the system and the relative distortion of all the elastic elements which connect the masses. It might be considered as a picture of the system just as it reaches its maximum displacement from the position of static equilibrium during the vibratory motion. All the masses in the system are vibrating with the same frequency in the same simple harmonic manner. The normal elastic curve gives a means of calculating the maximum kinetic energy in terms of the unknown frequency and the relative amplitudes of motion. The same picture indicates the data necessary to calculate the potential energy stored in the elastic elements at the point of maximum distortion.

The importance and usefulness of Rayleigh's method for calculating fundamental natural frequencies lies in the fact that the normal elastic curve need not be known accurately. It can

be drawn approximately so as to satisfy the necessary end conditions in the real system. From this approximate normal elastic curve an approximate value of the natural frequency can be calculated. The calculated value will always be too high, but if the arbitrarily chosen normal elastic curve satisfies the real end conditions and is not too badly distorted, the calculated frequency will be close to the actual value.

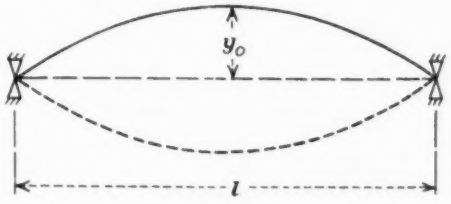

FIG. 8

An elastic beam of constant cross section simply supported on two bearings at its ends can execute an infinite number of modes of free vibration about its position of static equilibrium. The lowest frequency mode of motion will have a normal elastic curve such as shown in Fig. 8. This curve satisfies the conditions that the amplitude of motion at the supports must be zero and it has the general shape of the beam at its maximum excursion from the line of static equilibrium, which is represented here by the straight line between the two supports. Analytically this normal elastic curve could be described quantitatively approximately by several functions. Among them, the following would be possible

$$y' = y_0 \sin \frac{\pi x}{l} \quad [18]$$

The vibratory motion at any point x along the beam then could be given as

$$y = y_0 \sin \frac{\pi x}{l} \sin pt \quad [19]$$

The total maximum kinetic energy of all the particles in the beam will be

$$T_{max} = \frac{1}{2} \frac{\gamma A}{g} \int_0 \left(\frac{\partial y}{\partial t}\right)^2_{max} dx \quad [20]$$

The total maximum potential energy of strain in the entire beam is

$$U_{max} = \frac{1}{2} EI \int_0^l \left(\frac{\partial^2 y}{\partial x^2}\right)^2_{max} dx \quad [21]$$

T_{max} will contain p^2 and U_{max} will not; therefore, the equation $T_{max} = U_{max}$ can be solved for p^2.

For $y = y_0 \sin (\pi x/l) \sin pt$

$$T_{max} = \frac{1}{2} \frac{\gamma A}{g} y_0^2 p^2 \int_0^l \sin^2 \frac{\pi x}{l} dx \quad [22]$$

$$U_{max} = \frac{1}{2} EI y_0^2 \frac{\pi^4}{l^4} \int_0 \sin^2 \frac{\pi x}{l} dx \quad [23]$$

and

$$p^2 = \frac{\pi^4 EIg}{\gamma A l^4} \frac{\int_0^l \sin^2 \frac{\pi x}{l} dx}{\int_0^l \sin^2 \frac{\pi x}{l} dx} = \frac{\pi^4 EIg}{\gamma A l^4} \quad [24]$$

The frequency is seen to be independent of the actual value of y_0.

Static-Deflection Method for Calculating Natural Frequencies

Rayleigh's method can be applied with the static deflection of the system used in the place of the normal elastic curve. Fig. 9

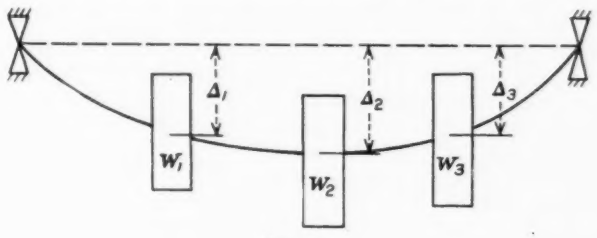

FIG. 9

shows a system in which this procedure can be used. The displacement of each mass is assumed to be

$$y_n = \Delta_n \sin pt \quad [25]$$

$$U_{max} = \Sigma \frac{1}{2} W \Delta_n \quad [26]$$

$$T_{max} = \Sigma \frac{1}{2} \frac{W}{g} \Delta_n^2 p^2 \quad [27]$$

and

$$p^2 = g \frac{\Sigma W_n \Delta_n}{\Sigma W_n \Delta_n^2} \quad [28]$$

In this method the actual values of the static deflection of each body are used for the Δ_n. These are best found by means of graphical integration. For the case of a single body this method gives the same result as Equation [11].

Natural Frequencies of Pendulous Bodies

Rayleigh's method is useful for pendulous bodies also. In these cases the kinetic energy consists of two parts—the linear kinetic energy of the oscillating mass associated with the linear velocity of the center of gravity and the kinetic energy of the body rotating about an axis perpendicular to the plane of motion and passing through the center of gravity. The potential energy depends on the weight of the body and the height of the center of gravity above the lowest possible position it can have.

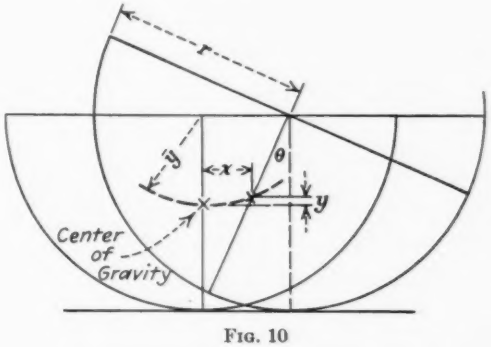

FIG. 10

Fig. 10 shows half of a circular cylinder rolling on its cylindrical surface. The natural frequency of its oscillation can readily be found by the energy method.

The mass of the semicylinder is

$$m = \frac{\pi\gamma l r^2}{2g}; \text{ and } i_0 = \frac{\pi\gamma l r^4}{4g}\left(1 - \frac{32}{9\pi^2}\right)$$

The coordinates of the center of gravity using the position of static equilibrium as the origin are

$$x = r\theta - \bar{y}\sin\theta \quad [29]$$

$$y = \bar{y} - \bar{y}\cos\theta \quad [30]$$

in which $\bar{y}$ is the radial distance between the center of the cylinder and the center of gravity and θ is the angle through which the semicylinder has rolled.

The oscillation of the cylinder is

$$\theta = \theta_0 \sin pt \quad [31]$$

$$\dot{\theta} = \theta_0 p \cos pt \quad [32]$$

$$\dot{x} = r\dot{\theta} - \bar{y}\cos\theta\dot{\theta} \quad [33]$$

$$\dot{y} = \bar{y}\sin\theta\dot{\theta} \quad [34]$$

The linear velocity of the center of gravity is v and

$$v^2 = [(r - \bar{y}\cos\theta)^2 + \bar{y}^2\sin^2\theta]\,\dot{\theta}^2 \quad [35]$$

and

$$v^2_{max} = (r - \bar{y})^2\theta_0^2 p^2 \quad [36]$$

$$T_{max} = \frac{1}{2}m(r - \bar{y})^2\theta_0^2 p^2 + \frac{1}{2}i_0\theta_0^2 p^2 \quad [37]$$

$$U_{max} = mg\bar{y}(1 - \cos\theta_0) = \frac{1}{2}mg\bar{y}\theta_0^2 \quad [38]$$

From this

$$p^2 = \frac{mg\bar{y}}{m(r - \bar{y})^2 + i_0} \quad [39]$$

Amplitude at Resonance—Energy Method

Wherever the energy lost per cycle can be calculated or measured and expressed as a function of the amplitude of motion, it is possible to estimate resonance amplitudes of motion. Whenever a force $P = P_0 \sin \omega t$ acts on a body of one degree of freedom, it causes a motion $x = x_0 \sin(\omega t - \phi)$. The energy put into the moving body during each cycle is $W = \pi P_0 x_0 \sin\phi$. At resonance, if the damping forces are not large, $\sin\phi = 1$. Therefore, the maximum value of energy input per cycle occurs at resonance and is

$$W = \pi P_0 x_0 \quad [40]$$

The energy lost per cycle, in any system that can be disturbed in its lowest-frequency vibration, can be measured from the free vibration record if the original store of potential or kinetic energy can be estimated. If this energy loss per cycle is a function of x_0 such as $W = mx_0^n$, the amplitude at resonance will be

$$x_0 = \left(\frac{\pi P_0}{m}\right)^{\frac{1}{n-1}} \quad [41]$$

This method leads to an indeterminate result when $n = 1$; n has this value in the case of pure Coulomb damping where the output per cycle is $W = 4Fx_0$, in which F is the friction force. If a system could have pure Coulomb friction with no other type of damping present, its amplitude at resonance would approach infinity (mathematically speaking).

For some types of damping, such as that caused by viscous friction forces or internal stress damping, it is possible to calculate the over-all loss of energy per cycle as a function of x_0. In such cases estimates can be made of amplitudes at resonance before the structure leaves the design stage.

Discussion

The Forces Required for Rolling Steel Strip Under Tension[1]

W. O. Clinedinst.[2] The author's solution of the differential equation of rolling by assuming the surface friction to be proportional to the slip velocity presents excellent possibilities. As well as giving distributions of contact pressures which closely approach those obtained experimentally by E. Siebel and W. Lueg,[3] it results in an expression which has the distinct advantage of being a continuous algebraic function from which expressions for the separating force and rolling moment can be obtained by direct integration. Such expressions coordinated to existing rolling-mill test data would certainly be of great value to rolling-mill designers.

Dr. Nádai is to be highly commended for his thorough analysis of the problem of rolling and has contributed much toward its further development.

Creep, Elastic Hysteresis, and Damping in Bakelite Under Torsion*

A. L. Kimball.† It seems to the writer that the agreement between the specific damping capacity in the dynamic and static tests is very good indeed. This brings out more clearly than ever that the damping effect in the case of a vibration is of the same character as the hysteresis phenomena observed by the authors in their static tests. Furthermore, it shows that the speed with which the strain cycles are executed has practically no effect on the frictional loss per cycle.

TABLE 1

Material	Log dec. δ	Specific damping capacity, ψ
Rubber, 90 per cent pure[a]	0.26	0.13
Celluloid	0.045	0.0225
Tin, swaged	0.129	0.0645
Maple wood	0.022	0.011
Zinc, swaged	0.020	0.010

[a] Vibration test.

In Table 1 is given a series of values of the specific damping capacity of a number of materials, as obtained by a special method described in reference (5).

Recent papers bearing on this subject which have interested the writer considerably are referred to at the close of this discussion. The papers by Zener represent the viewpoint of a mathematical physicist and are decidedly analytical in character. Nevertheless, it seems that they deserve careful study by the serious worker, in this field, who is mathematically inclined.

Numerical and Graphical Method of Solving Two-Dimensional Stress Problems[1]

L. F. Richardson.[2] Besides the work of Thom, to which the authors refer, there is a much earlier paper[3] by the present writer where the same differential equation is treated, though without the conformal mapping used in this paper. Again the problem of the tension member with semicircular notches was treated long ago by a graphical method for drawing the contours of the stress function.[4] The former of these two old papers has been consistently ignored by later writers on similar subjects, who include Thom, as aforesaid, Southwell,[5] and Temple.[6]

Authors' Closure

The authors wish to thank Dr. Richardson for calling their attention to his papers on the use of finite differences in problems involving partial differential equations. The paper by Messrs. R. Weller and G. H. Shortley which appears in the same issue of the Journal of Applied Mechanics (page A-71) refers to

the method as due to H. Liebmann.[7] Dr. Richardson's papers, antedating Liebmann's treatment by some nine years, clearly establish his priority.

A Theory of Flexure for Beams With Nonparallel Extreme Fibers[1]

J. N. Goodier.[2] The stress distributions discussed by the author are of the plane-stress type. They are based on the supposition that the three components of stress (σ_z, τ_{rz}, $\tau_{\theta z}$), which might be found on the plane faces of the uniform plate are zero throughout. This will, as a rule, be reasonably close to the truth only for thin plates. It has been widely supposed that Filon's "generalized plane stress" offers some escape from this restriction, but it can be shown that generalized plane stress has actually no wider range than simple plane stress.[3] This question of thickness arises in the paper in the application to the bend of a rigid frame, with a curved inner flange. The flanged part cannot be regarded as thin. Nevertheless we should not expect the three stresses which are neglected to have appreciable magnitude when the loads merely cause bending, and the agreement of the author's results with test results appears to confirm this point of view. His success with this problem seems to dispose of a structural element which has hitherto been difficult to deal with in a convincing manner.

F. C. Roop.[4] In connection with the author's example of the application of his theory to a plate girder with nonparallel flanges, it is of interest to examine the values of the principal stresses and of the maximum shearing stresses. Since a force applied in any direction at the edge of the wedge produces no shearing stresses on radial and circumferential elements, it is only in the case of loading by a couple that the radial stresses given by the author are not themselves principal stresses.

For couple loading, expressions for the algebraically greatest principal stress and the maximum shearing stress are found by substituting from the author's Equations [20] and [21] (together with $\sigma_{\theta z} = 0$) in the well-known formulas for these quantities. By differentiating these expressions with respect to θ, equating the derivatives to zero, solving the resulting equations, and discarding those solutions which either correspond to minima or give values of θ greater than α, expressions are arrived at which give the value of the coordinate θ at which the greatest values of the quantities in question occur. The algebraically least principal stress for any θ is the negative of the greatest principal stress for $-\theta$, because of the symmetrical nature of the stress distribution about the polar axis.

The analysis, according to the foregoing procedure, of the expression for the greatest principal stress σ_{p3} shows that no solution of $\partial\sigma_{p3}/\partial\theta = 0$ corresponding to a maximum of σ_{p3} can be found which gives θ less than α unless $\alpha > \alpha_c$, where

$$\alpha_c = \frac{1}{4}\tan^{-1}\left(-\frac{2A_f}{tr}\right);\quad 22^1/_2 \text{ deg} \leq \alpha_c \leq 45 \text{ deg} \ldots [1]$$

Consequently, when $\alpha \leq \alpha_c$, the greatest value on any one circular-cylindrical section occurs at $\theta = \alpha$. When $\alpha \geq \alpha_c$, the analysis shows that the value ψ of the coordinate θ at which the maximum of σ_{p3} occurs is given by

$$\psi = \frac{1}{2}\cos^{-1}\frac{\sqrt{1+8s^2}-1}{4s};\quad 22^1/_2 \text{ deg} \leq \psi \leq 45 \text{ deg} \ldots [2]$$

where $s = (2A_f/tr)\sin 2\alpha - \cos 2\alpha$.

Substituting in the expression for σ_{p3} the value of θ at which the maximum of σ_{p3} occurs gives the maximum principal stress $\sigma_{p3\,\max}$. The resulting expressions for $\sigma_{p3\,\max}/\sigma_{r3\,\max} = B$ (see following the author's Equation [20]) are

For $\alpha \leq \alpha_c$

$$B = \frac{1}{2}\left[1 + \sqrt{\left\{1 + \left(\frac{2A_f}{tr}\right)^2\right\}}\right] \ldots [3a]$$

For $\alpha_c \leq \alpha \leq 45$ deg

$$B = \frac{1}{2}\frac{\sin 2\psi}{\sin 2\alpha}(1 - \sec 4\psi) \ldots [3b]$$

For 45 deg $\leq \alpha \leq$ 90 deg

$$B = \frac{1}{2}\sin 2\psi(1 - \sec 4\psi) \ldots [3c]$$

These results are shown in Fig. 1 of this discussion, in which the coordinates α (half wedge angle) and $\frac{A_f}{A_f + tr\alpha}$ (relative flange area) should be regarded as two independent variables. Each point in the figure represents a plate girder having values of α and

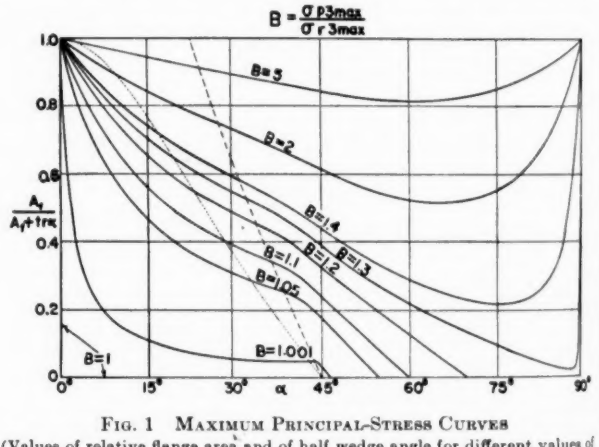

Fig. 1 Maximum Principal-Stress Curves
(Values of relative flange area and of half wedge angle for different values of the ratio of maximum principal stress to maximum radial stress for a wedge-shaped plate girder loaded by a couple.)

$A_f/(A_f + tr\alpha)$ given by the coordinates of the point, and lies on some curve B = const, which gives the value of B for this plate girder. The dashed line represents plate girders for which $\alpha = \alpha_c$ (see Equation [1] of this discussion).

As an example, a plate girder of half wedge angle 22.92 deg ($\alpha = 0.4$), with 55 per cent of its area in the flanges $\left(\frac{A_f}{A_f + tr\alpha} = 0.55\right)$ is seen to have a maximum principal stress 20 per cent in excess of the maximum radial stress ($B = 1.2$); furthermore, this maximum principal stress occurs at $\theta = \alpha$, just inside the junction between the (concentrated) flange and the web, since the representative point for this girder lies to the left of the dashed line.

[2] Professor of Mechanics, Cornell University, Ithaca, N. Y.

[3] "On the Problems of the Beam and the Plate in the Theory of Elasticity," by J. N. Goodier, Transactions of the Royal Society of Canada, vol. 32, 1938, pp. 65–88.

[4] Assistant Physicist, National Bureau of Standards, Washington, D. C.

For $\alpha \geq 45$ deg, the curves B = const in Fig. 1 also represent ψ = const, the correspondence being as follows:

B	ψ, deg	B	ψ, deg
1.001	43.78	1.3	29.98
1.050	36.82	1.4	28.93
1.100	34.30	2.0	26.05
1.200	31.57	5.0	23.63

Dividing the values of $f_3/\sigma_{r3\,max}$ (see third equation following the author's Equation [20]) by B gives values of $f_3/\sigma_{p3\,max}$.

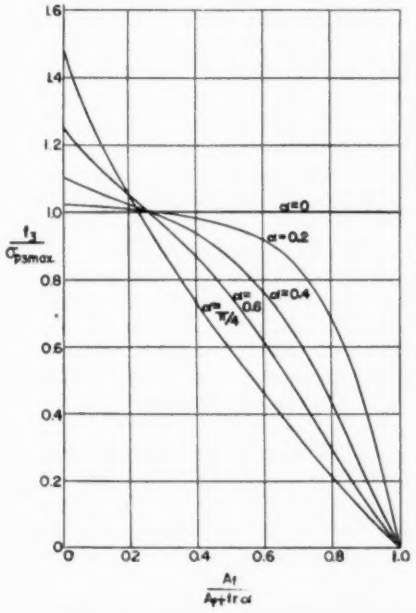

FIG. 2 COUPLE-LOADING CURVES

(Ratio of maximum stress by the ordinary beam theory to maximum principal stress by the wedge theory for all values of relative flange area and for different values of the half wedge angle of a wedge-shaped plate girder loaded by a couple.)

These are plotted in Fig. 2 of this discussion. By taking the same example previously given in this discussion, it is seen that while the maximum fiber stress by the ordinary theory is only 2.2 per cent (see Fig. 4 of the paper) less than the maximum radial stress by the present theory, it is 18.5 per cent less than the maximum principal stress by this theory, shown in Fig. 2 of this discussion. The concurrence of the curves in Fig. 2 at the point (1, 0) is due to the fact that, as the relative flange area approaches 100 per cent, the web becomes vanishingly thin, and the shearing stresses increase without limit.

In the case of the maximum shearing stress τ_{p3}, an analysis similar to the foregoing one in this discussion shows that the greatest value ($\tau_{p3\,max}$) of τ_{p3} on any one circular-cylindrical section occurs at the polar axis ($\theta = 0$) in case $\alpha \geq \alpha_s$, where, for B = const (see Fig. 1 of this discussion), α_s is related to α_c (Equation [1] of this discussion), by the expression

$$\alpha_s = 2\alpha_c - 45 \text{ deg} \quad [4]$$

In this case, the value of $\tau_{p3\,max}$ is equal to $\tau_{r\theta 3\,max}$ (see following the author's Equation [21]), since no normal stresses act at points on the polar axis (Equation [20]). When $\alpha \leq \alpha_s$ the value of $\tau_{p3\,max}$ is given by

$$S = \frac{\tau_{p3\,max}}{\sigma_{p3\,max}} = 1 - \frac{1}{2B} \quad [5]$$

and occurs at $\theta = \alpha$; see Equation [3a] of this discussion.

The dotted line in Fig. 1 of this discussion represents plate girders for which $\alpha = \alpha_s$, and in the region to the left of this line, the curves B = const are also curves for S = const, the correspondence being as follows:

B	S	B	S
1.000	0.500	1.3	0.615
1.001	0.501	1.4	0.643
1.050	0.524	2.0	0.750
1.100	0.545	5.0	0.900
1.200	0.583		

It is interesting to note that when $\alpha = \alpha_s$, τ_{p3} is independent of θ.

It must be remarked that in the case of a plate girder, the load on which is equivalent to forces at the edge of the wedge in addition to a couple, the foregoing results cannot be directly applied. This is true because the principal stresses will not in general act in the same directions in the combined case as in pure couple loading, and consequently they cannot be computed for the combined case by simple addition of their values for the cases which are superposed to produce the combined case.

AUTHOR'S CLOSURE

The author is indebted to Mr. Goodier for pointing out explicitly some of the limitations of the theory of plane stress when applied to cases in which the components of stress in a direction normal to the "plane of stress" are not all zero. These components were considered implicitly, but it would have been well to mention them.

Mr. Roop has gone as far as it is practicable to go in considering maximum normal and shearing stresses in the literal solution. His discussion adds welcomed completeness to the paper.

Clamped Rectangular Plates With a Central Concentrated Load[1]

EVERETT O. WATERS.[2] The author has made a very interesting use of successive-approximation methods in solving a set of linear simultaneous equations. During the last year, the writer was confronted with the task of solving sets of such equations in connection with the general problem of pressure distribution in a journal-bearing oil film, and found that when the set contained more than four equations he could get better accuracy and speed by successive approximation than by the "precise" methods usually taught in algebra textbooks.

TABLE 1 SUCCESSIVE-APPROXIMATION EQUATIONS

FIRST APPROX.	r	+ 12s	+ 13t	+ 14u	+ 15v	+ ..... = 01

	.	.	.	.	.	.
	.	.	.	.	.	.
	.	.	.	.	.	.

Briefly, the equations had the form given in Table 1 of this discussion. They are characterized by unity coefficients on a major

[1] By Dana Young. Published in the September, 1939, issue of the JOURNAL OF APPLIED MECHANICS, Trans. A.S.M.E., vol. 61, 1939, p. A-114.

[2] Associate Professor of Mechanical Engineering, Yale University, New Haven, Conn. Mem. A.S.M.E.

diagonal; all other coefficients are less than unity and rapidly approaching zero in directions downward and to the right from the major diagonal.

In these equations, the digits are not numbers in the conventional sense, but are position symbols for numbers that have given values less than unity. For the first approximation, one upper-left term only is used, and $r = 01$; for the second approximation, four upper-left terms are used; for the third, nine upper-left terms, etc. To obtain any approximation after the first, the values of the unknowns from the last preceding approximation are substituted in the lowest equation considered, and this equation is solved for the last unknown occurring in it; then the next higher equation is solved for the next last unknown, and so on until the highest equation and the first unknown are reached. For example, if the second approximation gives $r = r_2$, $s = s_2$, then the third approximations are

$$t_3 = (03) - (31)(r_2) - (32)(s_2)$$
$$s_3 = (02) - (21)(r_2) - (23)(t_3)$$
$$r_3 = (01) - (12)(s_2) - (13)(t_3)$$

After as many approximations have been made as there are unknown quantities, the method may be repeated successively for the full set of equations until the desired refinement of accuracy has been attained.

One great advantage of this method lies in the fact that all division is eliminated; consequently, there is complete avoidance of the accumulation of errors caused by dropping significant figures of doubtful importance, as happens when "precise" methods of solution (other than the unwieldy determinantal method) are used. The rapidity with which the approximations converge—if indeed convergence exists—must of course depend upon the relative values of the coefficients. This involves a mathematical investigation which the writer has not yet had time to make in general terms, although it appears that the only absolute requirement in the special case of two unknowns is

$$1 > (21)(12) > -1$$

It is always possible, and easy, to check any computation by substitution in the left side of each equation and comparison of the resulting sum with the corresponding right side. In every case where the writer has used the successive-approximation method this check has been made, and the comparison has been surprisingly good.

R. L. MOORE.[3] Because of the author's reference to an experimental investigation[4] paralleling certain phases of his analytical study, it would have been of interest if comparisons had been made where possible between the results of the tests and his theory. Such comparisons would have revealed two interesting differences:

1 That the maximum stresses observed in the tests were found directly under the concentrated loads applied and not at the edges of the plates as the author[1] has indicated.

2 That the stresses under the loads were very sensitive to the degree of load concentration, a factor which the author has not considered.

Except in cases where a plate is continuous over a number of panels, similarly loaded, a condition of 100 per cent fixity at the edges is usually difficult to obtain. In the tests referred to,[4] the edges of the aluminum-alloy plate specimens were clamped between pairs of $7 \times 3^1/_2 \times 1$-in. steel angles, thereby providing apparent degrees of edge fixity for the $^1/_2$-in. and 1-in-thick plates of 90 and 65 per cent, respectively. Having measured stresses and deflections under the load for both simply supported and clamped edges, however, it should be possible to estimate by proportion the corresponding values for completely fixed edges.

Table 2 of this discussion gives a summary of maximum measured stresses and deflections for four different sizes of aluminum-alloy plates with central loads distributed over a 2×2-in. area, taken from the experimental investigation previously referred to.[4] Included with these data are estimated values for completely fixed edges and the corresponding computed maximum stresses and deflections obtained from the data given in the author's paper.[1] As will be noted, the computed stresses at the edges of the plates ranged from only 37 to 53 per cent of the values estimated at the center, directly under the load. Obviously the author's solution does not give the maximum bending moments, as he so states. The computed stresses given in Table 2 of this discussion are in fair agreement, however, with those measured near the edges of the plates tested, where the effect of the degree of load concentration is not significant. The center deflections are likewise not sensitive to load concentration and consequently the computed values given in Table 2 are in reasonably close agreement with the measured values.

A. NÁDAI.[5] The solution of the problem of the clamped rectangular plate carrying a single concentrated load in its center was expressed by a sum of three elastic surfaces

$$w = w_1 + w_2 + w_3$$

in which the first term w_1 was identified with the elastic surface of a rectangular plate carrying a concentrated load P in the center and satisfying Navier's boundary conditions $w_1 = 0$ and

$$\Delta w_1 = \frac{\partial^2 w_1}{\partial x^2} + \frac{\partial^2 w_1}{\partial y^2} = 0$$

along the edges. This first portion of the solution contains a singularity at the center of the plate, where the bending moments become logarithmically infinite, while the terms w_2 and w_3 have no singularities in the interior or along the edges of the plate. It may be of interest to note that w_1 is an important solution of the

theory of flat plates, deserving of being utilized. Bergsträsser[6] has developed exact means for computing not only the values of $w_1(x, y)$ but also of the bending moments corresponding to this elastic surface for any position of the concentrated load. Infinite series representing the moments in the case of a concentrated load are known not to converge well. In the paper quoted,[6] use of a remarkable property of a special case of $w_1(x, y)$ was made. This latter occurs when in the rectangular plate one pair of the sides becomes infinite ($b = \infty$). For such a rectangular plate, that is for an infinitely long strip of the width a which is loaded by a concentrated force P in the interior and which is satisfying the boundary conditions $w_1 = 0$ and $\Delta w_1 = 0$, it is possible to compute the bending moments by finite expressions, because they depend on the surface Δw_1 and on the derivatives of Δw_1. This surface Δw_1 being a harmonic function (Green's function for the infinitely long strip) can be constructed by conformal mapping. Several cases were computed by Bergsträsser.[6]

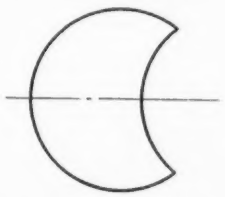

FIG. 1 CLAMPED PLATE HAVING TWO RECTANGULAR CORNERS

The problem of the clamped rectangular plate has been the subject of a series of important investigations during the last decades, both by mathematicians and engineers, and further attempts to express the results of these investigations in a convenient manner for the direct use in engineering applications, as in the paper under discussion, must be particularly commended.

There is another interesting side of the problem of the rectangular plate with clamped edges which, it seems to the writer, would deserve some attention and which possibly is ready for an analytical attack. The mathematical nature of the solution of $\Delta\Delta w = f(x, y)$ around a plate corner having two built-in edges has to the knowledge of the writer never been clarified sufficiently or more fully discussed. I believe that W. Ritz[7] in one of his early studies on clamped plates made the remark that it may not be possible around a corner with clamped edges to develop a solution of $\Delta\Delta w = 0$ or $= f(x, y)$ into an infinite series of terms not unsimilar to those used in the case when along the two edges the conditions $w = 0$ and $\Delta w = 0$ have to be satisfied. Ritz did not use infinite series, but a finite number of terms. In other words, it would be of considerable theoretical interest to know more definitely whether Ritz is right or whether on the contrary a particular solution of $\Delta\Delta w = 0$ or of $\Delta\Delta w = f(x, y)$ can be constructed or found, which would satisfy the conditions $w = 0$ and $\partial w/\partial n = 0$ along perpendicular curves. One suggestion for mathematicians who might possibly become again interested in some of these questions will be mentioned. By searching for an example among the known particular solutions of $\Delta w = 0$ and of $\Delta\Delta w = 0$ when expressing them by means of the curvilinear bicentric coordinates derived from certain transformations used in the theory of conformal mapping, it may perhaps be possible to satisfy the previously mentioned boundary conditions along two circles which are perpendicular to each other. If the elastic surface of a uniformly loaded plate which has two circles for the edges and only two rectangular corners, as shown in Fig. 1 of this discussion, in which the conditions $w = 0$, $\partial w/\partial n = 0$ would have to be satisfied, could be established, the question would be answered. Means which were recently developed by Jeffery,[8] Mindlin,[9] and others could be utilized and seem to be available for this purpose.

AUTHOR'S CLOSURE

In his discussion, Professor Waters has given an interesting illustration of the use of a successive-approximation procedure for solving simultaneous equations. The author agrees that, in cases where the approximations converge rapidly, this method is superior to the so-called "precise" method. Dr. Nádai has made some valuable suggestions regarding further mathematical investigations for clamped plates. It is to be hoped that these may be followed up.

It would appear that Mr. Moore has misunderstood the results given in the paper. The moments given by Equation [14] are maximum *edge* moments and it is *not* stated nor implied that these are greater than the moment at the center under the concentrated load. The stresses in a plate at a concentrated load depend upon the area over which the load is distributed and upon the thickness of the plate. Since this problem has been treated at length by numerous investigators, as for example, Nádai,[10] Timoshenko,[11] Westergaard,[12] Holl,[13] and Woinowsky-Krieger,[14] it was not believed necessary to discuss the problem in this paper. In these references will be found values for the moments or stresses at a concentrated load for a simply supported plate which corresponds to the elastic surface w_1 as defined by Equation [3] in the paper. Then the results for a clamped plate are obtained by adding to the foregoing values the moments at the center corresponding to the functions w_2 and w_3 given by Equations [4] and [5]. Thus, from w_2 we find

$$(M_y)_{\substack{x=0\\y=0}} = -D\left(\frac{\partial^2 w_2}{\partial y^2} + \nu\frac{\partial^2 w_2}{\partial x^2}\right)\Bigg|_{\substack{x=0\\y=0}} = \sum_{m=1,3,5\ldots} A_m(-1)^{\frac{m-1}{2}}\frac{1-\frac{1}{2}(1-\nu)\alpha_m\tanh\alpha_m}{\cosh\alpha_m}$$

$$(M_x)_{\substack{x=0\\y=0}} = -D\left(\frac{\partial^2 w_2}{\partial x^2} + \nu\frac{\partial^2 w_2}{\partial y^2}\right)\Bigg|_{\substack{x=0\\y=0}} = \sum_{m=1,3,5\ldots} A_m(-1)^{\frac{m-1}{2}}\frac{\frac{1}{2}(1-\nu)\alpha_m\tanh\alpha_m-\nu}{\cosh\alpha_m}$$

The corresponding expressions for w_3 are similar. From these expressions can be found the desired center moments. For example, for a square plate, we find that the moment at the center due to the applied edge moments is $-0.0536P$. This is to be

added algebraically to the moment due to the load on a simply supported square plate to get the total moment at the center of a clamped square plate.

It may be of interest to compute the center moment for one of the experimental plates cited in Mr. Moore's discussion. Take for example the $1.062 \times 48 \times 48$-in. plate with a central concentrated load of 10,000 lb. For a simply supported square plate with a central concentrated load distributed over a circle of radius c, Timoshenko,[11] assuming that Poisson's ratio is 0.3, gives the moment at the center as

$$M = P\left(0.1034 \log \frac{a}{2c} + 0.0597\right)$$

in which expression a indicates the length of the side of the plate.

In the experimental plate the load was distributed over an area 2×2 in. square. It seems reasonable to assume that c may be taken as the radius of circle whose area is 4 sq in. Then we find the center moment equals $0.371P$ and the bending stress $\sigma = 6M/h^2 = 19{,}700$ lb per sq in., which compares with the experimental value of 19,600 lb per sq in. Then for the same plate with clamped edges we have the center moment $M = 0.371P - 0.0536P$ and the bending stress $\sigma = 16{,}900$ lb per sq in., which compares with the experimental value of 17,300 lb per sq in.

Book Reviews

A History of Science

A HISTORY OF SCIENCE, TECHNOLOGY AND PHILOSOPHY IN THE EIGHTEENTH CENTURY. By A. Wolf. The Macmillan Company, New York, 1939. Cloth, $6 \times 9^3/_4$ in., 815 pp., 345 illustrations, $8.

REVIEWED BY J. ORMONDROYD[1]

IN 1935 The Macmillan Company published Professor Wolf's "History of Science, Technology and Philosophy in the sixteenth and seventeenth centuries." Professor Wolf stated in the preface to that volume that it was only the first of four similar works to appear. The other three were to cover the same ground for the eighteenth century, the nineteenth century, and the ancient and medieval periods. The subject of this review is the second volume of the promised series. In external and internal appearance it is the exact twin to the first volume; but it contains 122 more pages of printed matter in order to cover the greater wealth of material offered by the eighteenth century. The numerous illustrations, depicting the prominent actors in the scientific drama and their work, along with the enormous number of citations from the original-source papers and publications, will make this completed work a "gold mine" for future historians of science.

The subject matter is arranged in five groups. The first includes mathematics, mechanics, astronomy, and closes with a discussion of astronomical and marine instruments developed during the eighteenth century. Next follow four chapters on the physical sciences of light, sound, heat, electricity, and magnetism. The section on the sciences is concluded by nine chapters which cover meteorology, meteorological instruments, chemistry, geology, geography, botany, zoology, and medicine.

The next seven chapters are of exceptional interest to an engineer, since they deal with the technological advances made during the eighteenth century. The chapters in this group discuss agriculture, textiles, building, transport, power plant, and machinery, the steam engine, mining and metallurgy, industrial chemistry, the making of lenses and specula, mechanical calculators, telegraphy, and other important technical activities which are not named in the chapter headings.

The last five chapters of the book review the eighteenth-century writings on psychology, social sciences, and philosophy.

From the purely scientific point of view, the eighteenth century was an "in-between" century. It was kept busy extending and completing the work which the masters of the previous century had started. It also was preparing the ground for the magnificent generalizations in electricity, thermodynamics, and chemistry which were to appear in the nineteenth century. Men like Copernicus, Kepler, Galileo, and Newton stood out like giants in the sixteenth and seventeenth centuries, their achievements were such that whole chapters had to be devoted to their work in the earlier volume. No single individual in the eighteenth century was important enough by himself to be the subject of a separate chapter in the present book.

If the century was lacking in "stars," it more than made up for that in its awakening "humanism." The eighteenth century saw the beginning of a conscious effort to enlighten everyone as to the results of the new thought. The urge which ultimately led to almost universal education started in this "age of enlightenment and reason." Science and technology began a very conscious cooperation in that century. In that century technology took such a vigorous new start in utilizing natural energy to replace the physical work of man and beast, and in devising mechanisms and processes for manufacturing things useful to man, that we designate it the birth century of the "industrial revolution." Professor Wolf's introductory chapter draws in broad outline the character of that century so full of glorious dreams for a happy future. These dreams were never fully realized and in our own century some of them are farther from realization than they were then.

Perhaps the most interesting section of the book for our profession deals with the emergence of the modern engineer. Most of our early predecessors were mechanics untutored in the schools that existed. From their own native intelligence and experience they built roads, bridges, lighthouses, machinery, and devised processes. They often provided the stones with which nineteenth-century science was to build. Two such men were typical and deserve mention for their importance in introducing the scientific method into practical affairs.

John Smeaton (1724–1792) is mentioned in eleven different places in this volume. "He was at once a craftsman, consulting engineer, and man of science—all of high order." He built devices for measuring the expansion of solids, improved the string hygrometer, anticipated Franklin in constructing the lead-coated glass plate condenser, consulted on bridge construction, and built lighthouses. But he is interesting mainly for his careful experimental work on the efficiency of water wheels, windmills, and pre-Watt steam engines and for his studies of energy storage in flywheels. In his studies of windmills, water wheels, and flywheels

[1] Professor of Engineering Mechanics, University of Michigan, Ann Arbor, Mich. Mem. A.S.M.E.

he made use of the exceedingly modern device of models and anticipated Langley's rotating-arm "wind tunnel." Smeaton's studies permitted him to raise the efficiency of the Newcomen engine from around 0.4 to 1.1 per cent, which was about the best that the pre-Watt engines ever did. He improved the efficiency of both water wheels and windmills also.

The careless modern reader might ask why Smeaton did not deduce his results (at least on water wheels) from the existing Newtonian mechanics. The answer to that is that the Newtonian mechanics of his day were not prepared to give him the information he wanted. It was almost a hundred years after Smeaton's heyday that both mechanic and scientist meant the same thing when they said "work" and "power." The word "efficiency" in its present meaning could not even exist until thermodynamics became a full-fledged science. Even the word "force," so clearly defined by Newton, retained a confused meaning many years after Smeaton's death. As late as 1900 the word "force" can be found in printed literature having the meaning of "energy." Far from having missed an opportunity to apply deductively a well-established science, Smeaton was in reality helping to lay the foundation for the modern range and connotation which the science of mechanics has only recently attained.

Smeaton's younger French contemporary, Charles Augustin Coulomb (1736–1806) was a military engineer whose scientific work all grew out of practical projects. The attempt to improve the magnetic compass led to his quantitative laws of attraction and repulsion for electrostatic charges and for magnetic poles. The measurement of these in turn led to the invention of the torsion balance and the introduction of our modern theory of twisting in beams and rods. Coulomb put the beam-bending theory into its modern form, he founded our accepted theories of elastic arches, correctly worked out a theory of earthwork pressures, and introduced clearly the ideas concerning failure due to shear in materials—all in one study on the use of maximum and minimum ideas in "Statical Problems Applied to Architecture." Strangely enough, Coulomb's work on friction is passed over in silence in this volume.

Smeaton and Coulomb published in the proceedings of the leading scientific societies of their respective countries. They might well be considered as the spiritual ancestors of the Applied Mechanics Division. Many other names and accomplishments could be cited from the wealth of material in the volume.

No engineer who wishes to get an integrated picture of the scientific and technical history of his profession can afford to neglect Wolf's monumental history.

Thermodynamics

INCHLEY'S THEORY OF HEAT ENGINES. Edited and revised by H. Wright Baker, D.Sc. Longmans, Green and Company, New York, 1939. Cloth, 5¼ × 8½ in., xvi and 445 pp., 170 figs., $3.60.

REVIEWED BY JOSEPH H. KEENAN[2]

INCHLEY'S "Theory of Heat Engines" was first published in 1913. It was revised in 1920 by Dr. A. Morley "as a tribute to the memory of a former colleague," the original author having been killed in action in December, 1915. The present edition was prepared by Dr. H. Wright Baker who has made additions at the expense of the omission of the chapters dealing with kinematics and dynamics of engines.

Besides a foundation of thermodynamics the book includes discussions of hot-air engines, air compressors and motors, steam-engine cycles, reciprocating steam engines, nozzles and orifices, steam turbines, internal-combustion engines, refrigeration machinery, heat transfer, combustion, and testing of engines. The treatment of each of these subjects includes a generous number of numerical examples and a collection of problems for the student.

The chapters on reciprocating steam engines and internal-combustion engines are conscientiously detailed, though not exhaustive. The mathematics of heat transfer through solids is presented with unusual punctiliousness for a book of this nature. It would have been better, perhaps, to sacrifice some of it to a treatment of the mechanism of convection.

In the preface to the present edition it is stated that "No rigorous statement of thermodynamics has been attempted . . ." The implication that the author of a text on heat engines might well be excused if he omits a rigorous statement of thermodynamics is entirely defensible; but there is no defense for an author who does not build his work on a rigorous foundation of thermodynamics. In the list of symbols H is "a quantity of heat," while on page 69, H is a coordinate of a diagram of properties. This is the beginning of confusion that makes subsequent explanations long and involved. There are two pages devoted to the calculation of the dryness of steam after isentropic or adiabatic expansion and four and a half pages are devoted to the calculation of the end state after throttling.

The book is based largely on British source material. It includes many references to publications with which American engineers are not familiar and calls attention to test codes and reports by research committees of the British engineering societies.

Background to Modern Science

BACKGROUND TO MODERN SCIENCE. Edited by Joseph Needham and Walter Pagel. The Macmillan Company, Inc., New York, N. Y., and University Press, Cambridge, England, 1938. Cloth, 5¼ × 8¼ in., xii and 243 pp., $2.

REVIEWED BY J. ORMONDROYD[3]

BACKGROUND to Modern Science" goes over a familiar road, recording part of the history of scientific advances in the forty years between 1895 and 1935. The subject matter is handled in chapters each separately written by different authors. Each chapter is in itself a record of a lecture on the same subject delivered at Cambridge University in the year 1936. These lectures inaugurated an attempt to emphasize the importance of the history of science to the student of scientific subjects at Cambridge. The chief point of interest in the mode of presentation used is that the lecturers themselves were selected from the very group which made a large share of the advances discussed.

The advances in atomic physics are described by Lord Rutherford in two separate lectures which are reproduced in a single chapter. Incidentally, this address was the last delivered publically by Lord Rutherford before his death. F. W. Aston also discusses certain phases of atomic knowledge. W. L. Bragg outlines crystal physics and Sir Arthur Eddington gives the history of the rise of relativity. In these four chapters no philosophy of science is attempted. The contributions merely list the various experiments which turned out to be important historically.

If the chapters listed here were the sole contents of the book, it would not be a book worth reading—important as the contributors are. After all, we have read about these discoveries in a hundred other places, and have seen them more extensively treated. But the last four chapters of the book *are* worthy of attention. They discuss the advances made in the biological sciences—material which has not found its way into the deluge of popular scientific treatises which has poured over

[3] Professor of Engineering Mechanics, University of Michigan, Ann Arbor, Mich. Mem. A.S.M.E.

us in the last few years. For this reason only one of the four lecturers on the biological sciences bears a familiar name. "Physiology and Pathology," by J. A. Ryle, "Parasitology and Tropical Medicine," by G. H. F. Nuttall, "Evolution Theory," by R. C. Punnett, and "Genetics," by J. B. S. Haldane are the subjects and writers of the last four chapters in the book.

The eight chapters which deal with specific subjects in modern science are preceded by two general and introductory chapters. The second entitled "From Aristotle to Galileo" by Sir William C. Dampier outlines briefly the background of modern science, covering material that is treated in many other places. But the first chapter, entitled "Greek Natural Philosophy and Modern Science," written by F. M. Cornford, is very enlightening in spite of the apparent staleness of the subject. Professor Cornford's comparative analysis of the motives, objects, procedures, and methods of the Greek and modern sciences is one of the clearest and most concise to be found in the literature of scientific history.

Buckling of Bars

Die Knickfestigkeit Eines Zentrisch Gedrückten Geraden Stabes im Elastischen und Unelastischen Bereich. By Arvo Ylinen, Technical Director of the State Aircraft Factory, Tampere, Finland. Druckerei-A.G. der Finnischen Literaturgesellschaft, Helsinki, 1938. Paper, 6¼ × 9¾ in., 131 pp., 53 figs., 70 Finnish marks.

Reviewed by S. Timoshenko[4]

IN DISCUSSING lateral buckling of compressed prismatical bars two cases are usually considered (1) buckling within the elastic region, and (2) buckling within the inelastic region. In the first case, the known Euler's formula gives the value of the critical compressive stress; in the second case, the critical value of the stress is usually determined by applying one of the existing empirical formulas. Engesser was the first who indicated that the problem of buckling in both regions can be treated by using the same formula if only the notion of the reduced modulus is introduced. The critical stress then is

$$\sigma_{cr} = \frac{\pi^2 E'}{\lambda^2} \quad \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

where $\lambda = l/k$ is the slenderness ratio and $E' = d\sigma/d\epsilon$ is the reduced modulus derived from the tension compression test diagram of the material of the column. Mr. Ylinen shows that for such materials as steel and wood it can be assumed that

$$E' = E\left[1 - \left(\frac{\sigma}{\sigma_{yp}}\right)^n\right] \quad \ldots\ldots\ldots\ldots\ldots [2]$$

in which the constant n must be properly chosen for each kind of material. A table of values of n for several important materials is given in the book. It is shown there also that the effect of strain-hardening and the influence of the shape of the cross section can be taken into consideration by a proper change of the magnitude of the constant n. Substituting the value of E' in formula [1], an expression for critical stress is obtained which is applicable for any value of slenderness ratio. The application of this expression in design of columns is shown and there finally is given a comparison of Equation [1] with various existing formulas. It is shown, for example, that by taking $n = 1$ the known Rankine's formula is obtained. In the last portion of the book the comparison of the formula with test data is given. The known experiments of Kármán, Roš, and Rein with steel columns can be brought in very good agreement with formula [1]. A satisfactory result is also obtained in applying formula [1] to the tests of wooden columns made in Finland.

The book contains several numerical tables simplifying the application of formula [1] in various cases and also diagrams illustrating the difference in the values of λ_{cr} as obtained by the empirical formulas and by the proposed formula [1]. The book will be of interest to engineers dealing with column design.

Steam Engine

A Short History of the Steam Engine. By H. W. Dickinson. University Press, Cambridge, England; The Macmillan Company, New York, N. Y., 1939. Cloth, 6 × 9¼ in., xii and 255 pp., 78 figs., $3.50.

Reviewed by C. Richard Soderberg[5]

LITERATURE on the history of science and technology has accumulated rapidly in recent years. Nostalgia for past ages, when the belief in the blessings of technological progress was still unshaken, is a natural consequence of the general attitude of hopelessness and despair at the inability of modern man to master his own destiny. It is pleasant to roam in the dusty archives from what now appears the golden age of our era.

Regardless of the impelling motive we are gradually beginning to appreciate the importance of the historical perspective of our technical advance. Much has been said about the failure of the scientist and the engineer to take an active part in the solution of our social and economic problems, and even the engineers themselves have come to regard this state of affairs with misgivings. It is not at all certain that the methods of the exact sciences have direct application to social problems, but if the engineer is to exert an effective influence on the solution of these problems, some of his urge to make history must be converted into intelligent contemplation of past history. This can only be accomplished by an educational process in which the engineer is gradually trained to give attention to the history of his specialty. On this basis the subject of the history of science and technology should be given a prominent position in the curricula of our universities. The lack of suitable literature for such courses has long been an obstacle to this, but is gradually being eliminated by the work of such men as Dickinson, Wolf, and others.

The author of the present treatise has already made a name for himself through his masterly productions on other phases of the history of steam power. The recent books on James Watt, Matthew Boulton, and Richard Trevithick represent a very high standard of performance in this class of literature.

The book under review is divided into two parts—part 1 covering the history of the reciprocating steam engine, and part 2 covering the history of the steam turbine. In the preface the author cites a few simple data which convincingly illustrate the fact that the importance of steam power was never greater than today. This is significant in view of the curious attitude held by many persons that the age of steam is past. The total annual consumption of electric power in the world is of the order of 1700.10^9 kwhr; of this nearly 95 per cent is generated by the combustion of fuel. The purpose of the volume is to trace the development which has taken place since Savery and Newcomen in the latter part of the seventeenth century first produced engines which supplanted the toil of men and animals.

The introductory chapter is a concise sketch of the social and economic conditions of England, out of which the development was precipitated. Here as in the latter chapters Mr. Dickinson has succeeded well in his endeavor to show that the invention of steam power did not arise spontaneously in any inventor's mind;

[5] Professor of Applied Mechanics, Massachusetts Institute of Technology, Cambridge, Mass. Mem. A.S.M.E.

it was a logical outgrowth of the needs of the time. For completeness one might wish for some references to the devices that actually were in use earlier, such as the devices in use in the mines of Sweden, but this perhaps belongs more properly to an earlier phase of man's mastery over nature.

In the succeeding three chapters the author deals with the developments that took place in connection with the work of Savery and Newcomen and particularly with the consolidation of position of the atmospheric engine in the period between Newcomen and Watt. It is probably a surprise to many engineers that Savery and Newcomen, although contemporaries, were probably not acquainted with one another, and certainly did not cooperate in their work. Another fact, not usually appreciated, is that the Newcomen engine had existed for about half a century as an important industrial device before Watt arrived on the scene.

The following chapter is devoted to Watt's contribution to the development. This was of such fundamental character that the invention of the steam engine has often been erroneously credited to him. This error is effectively dispelled by the author without any loss to Watt's prestige. A new era was inaugurated through the work of Watt and Boulton, an era which in some respects may be regarded as continuing into the latter part of the nineteenth century, when the steam turbine arrived on the scene.

The remaining chapters of part 1 cover the important developments of the reciprocating steam engine during this period as well as the parallel evolution of land boilers. The concluding chapter is devoted to the "philosophy of the steam engine" an admirable discussion of the seesaw workings of empirical mechanical developments and theoretical advances. The author emphasizes the important fact that the inception of a development like that of the steam engine is necessarily empirical; the resulting advances, although often stumbling and imperfect, give rise to a search for a more rational outlook which gives incentive to the search for more exact knowledge.

The first chapter on the history of the steam turbine gives a historical perspective of the early consideration of this device up to and including the achievement of Parsons. Watt's discussion of the turbine invention by Baron von Kempelen is interesting, not only because of his clear analysis of the turbine problems, but also in illustrating the fact that Watt was led by selfish interest to hope that "without God makes it possible for things to move at 1000 feet p^{r} it cannot do much harm."

The remaining chapters cover the work of other turbine and boiler pioneers down to the present time. His choice of leading pioneers is undoubtedly correct in that the basic turbine inventions were made by Parsons, De Laval, Curtis, Rateau, and Ljungström. It seems somewhat unfair, however, to leave out of this group the name of George Westinghouse who certainly pioneered in the introduction of the steam turbine in the U. S. A. It is true that Westinghouse did not produce any fundamentally new invention on the steam turbine, but his role in the beginning of the present century was, nevertheless, of outstanding significance. Nor does it seem entirely fair to leave out of the discourse such names as Emmett, Junggren, and Hodgkinson, although here he may be justified by the difficulty of encompassing the turbine history in a reasonable space. The excellent papers which were presented in 1936 before the A.S.M.E.[6] on turbine history in the U. S. A. could well have served as a reference for this important phase of turbine history.

In the conclusions the author presents some speculations on the probable future of power generation by entirely new methods. To these speculations he adds the following significant remarks: "The community would be well employed in making better use than it has done hitherto of the gifts that the scientist and the engineer have showered upon it; till then, further gifts would be in the nature of pearls before swine."

It will be evident that the reviewer considers this contribution to the history of steam power of outstanding value and interest.

Problems in Mechanics

PROBLEMS IN MECHANICS. Based on the original collection of L. V. Mestchersky. By G. B. Karelitz, J. Ormondroyd, and J. M. Garrelts. Engineering Science Series, edited by Earle Raymond Hedrick. The Macmillan Company, New York, 1939. Cloth, 6 × 9¼ in., ix and 271 pp., figs., $2.50.

REVIEWED BY ALVIN SLOANE[7]

THIS is a collection of some eight hundred problems intended for the first courses in engineering mechanics. An appraisal of its value as a manual or collection leads very rapidly to a consideration of the pedagogy of these courses and to the role which this collection, inherently so sound, may play in enhancing the teaching of elementary mechanics.

Engineering pedagogues, like Topsy, "just grow up." Most frequently, untrained in techniques of pedagogy, the engineering teacher is apt to consider formalizations of method as impedimenta, and his course may lack coordination within itself, or in the general educational pattern. While some aspects of formal teaching method may be stultifying, there can be no quarrel with contributions which integrate and coodinate subject matter. When, in his better aspect, the engineering teacher is alert to the accelerated pace of scientific and technological advance, he faces the difficult task of canalizing into the classroom a flow of subject matter adjusted so that it may be compatible with the intellectual level of his student audience; provocative, so that it may stimulate and inspire rise to higher levels; penetrating, so that the basic fundamental may be recognized and its grasp enhanced at each stage; and thorough, that the sure footing of mental discipline may serve in integrating an educational career.

In applied mechanics, the recent advances in explorations toward advanced objectives have received the prominent and primary attention of the leaders. On the educational firing line we find little supporting activity. The classroom too frequently is static in a dynamic, virile, expanding subject, or confused in its efforts to reconcile educational process with research progress.

It is, therefore, encouraging to find leaders of the caliber of Professors Karelitz, Ormondroyd, and Garrelts devoting attention to the necessity of implementing an advancing field with new generations of workers, effectively grounded in fundamentals, and conscientiously trained in methods of attack so that they may serve with distinction as they approach the upper ranks.

Their book, "Problems in Mechanics," is a vital contribution to orientation in the teaching of the undergraduate first courses in statics, kinematics, and dynamics (kinetics). It brings to such undergraduate courses a basis which is intended to serve as a supplement to the expositions offered in the usual textbooks, and to meet the challenge of proper preparation for later stages in the development of perspective and attitude toward engineering mechanics.

The teaching devices employed are conducive to proper and

[7] Assistant Professor of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, Mass. Mem. A.S.M.E.

vigorous growth—for example, illustrations which are sufficiently complete in detail to acquaint the student with the actual physical aspect of machine or structure, make the transition from abstractions to actualities effective—there has been too much "skeletonizing" of the problems by reduction to lines which psychologically creates a gap between the exposition of principle and the recognition of application of the same principle. Such devices stimulate through presentation of realities, always more intriguing than philosophical speculation in the mind of the embryonic engineer.

The problem material is carefully selected to encourage development; the range of difficulty includes careful treatment of simple, intermediate, and advanced material, and a group of illustrative examples is interspersed to suggest method of attack.

The kinematics section presents more extended treatment than is customary, recognizing the position of this factor in preparation for applications in kinetics. An additional factor of importance is provided in special sections devoted to bearing reactions, vibrations, oscillation, and impact. The inclusion of vibration problems of elementary nature at this educational stage adds a fundamental approach too frequently painstakingly avoided.

The material is coordinated, and a logical sequence employed throughout, so no difficulty of adaptation in classroom can arise.

In addition to the problem material, a résumé of the basic theorems of mechanics forms a first section of the book.

To this reviewer, it seems that this element is the only flaw, not because of its content, which is splendidly presented, but because this book can find its most effective use as a supplement, and not as a substitute for extended exposition of bases, in the case of students who should be equipped with a fuller text.

The space devoted might have been given to an expansion of the philosophy whose surface is but scratched in the preface, e.g., "the expositions of the principles and theorems of mechanics is of little practical value to the student unless he is constantly exercised in their application to actual problems. Only by this means can mechanics become a working tool for the future engineer."

Such an expansion, a discussion of the philosophical and disciplinary possibilities of this subject in encouragement of effective "straight thinking," and a penetrating analysis of the trend of thought in organizing method of attack would, from the pens of these authors, add an element of personal invitation and encouragement which the student too rarely finds in textbooks.

It would be well if this collection of problems could encounter a widespread reception in the classroom, for the orientation of the pedagogy of mechanics in its earliest stages is of vital concern. The textbook is the usual source of problem material, and textbook problems are frequently so intimately associated with the author's exposition that they lack universality. This collection, ramifying no particularized textbook, but written upon premises of universal application, deserves the opportunity of furthering the trend in engineering education, which seeks to establish strength in general fundamentals, and to avoid, in development stages, localization or specialization.

Fluid Mechanics

Mécanique des Fluides Appliquée. (Exercise numériques en vue des applications industrielles.) By A. Tenot. Dunod, Paris, 1939. Paper, $5^1/_2 \times 8^1/_4$ in. Tome III, Hydraulique et Hydrodynamique, viii and 183 pp., 48 figs. Tome IV, Production et Utilisation de la Vapeau d'Eau, viii and 106 pp., 26 figs., 1 plate. Price, each 45 fr.

Reviewed by Hugh L. Dryden[8]

As M. Caquot points out in his brief preface to this series of volumes, "modern theories of fluid mechanics have for some years been the possession of a small number of scientists, but their efficacy in the most diverse fields, such as aviation, ventilation, lubrication, turbine and pump design, have necessitated their use by an increasing number of engineers." M. Tenot brings the knowledge of these theories to engineers by the discussion of selected problems characterized by him as numerical exercises with a view to industrial application. The books are intended for the use of the Écoles Nationales d'Arts et Métiers, advanced technical schools, and industry. Since many American engineers are inexperienced both in the French language and in the use of the metric system, the book will be of primary interest to teachers of fluid mechanics as illustrating a method of instruction and a choice of types of problems to illustrate fundamental principles.

Volume 3 consists of 27 problems in hydraulics and hydrodynamics, as follows: Inclined venturi tube, vertical free jet with axial and spiral flow, sharp-edge weir, influence of compressibility of liquids, emptying of reservoir of variable section through sharp-edged orifice, jet from Pelton injector, diffuser with meridional flow, stationary vortex with and without spiral flow, flow in a spiral volute, spiral flow in a conical diffuser, flow in a diffuser with contravanes, design of a nozzle, siphon, flow in a pump-discharge line, force on an obstacle in a pipe line, functioning of discharge valve, theory of cavitation apparatus, reactions on an elbow from jet discharge, impact of jet on normal plate, deflector, forces on a gate valve, automatically closing gate valve, reaction of flow on walls of channel, pump characteristics, two pumps in parallel, operation of pump on a discharge line of known characteristics, exhaust blower of submarine Diesel engine.

These problems serve to illustrate the use of the equation of continuity, Bernoulli's equation for compressible and incompressible fluids, Pascal's law, the momentum principle, conservation of angular momentum, and so on. The author frequently calls attention to the approximate character of many of the computations and to the reasons for discrepancies between the computed and observed results. Reference is occasionally made to the author's earlier book entitled, "Leçons de mécanique-physique des fluides," for further information on fundamental principles.

Volume 4 contains 13 problems dealing with the production and utilization of steam. These relate to use of Mollier diagram, throttling and superheating, throttling of wet steam, steam turbine, nozzle, high-pressure and high-temperature turbine, low-pressure turbine, interstage superheating, experimental study of nozzle flow, experimental study of momentum loss in moving blades of turbine, reciprocating steam engine, condenser, Claude process for obtaining thermal energy from the ocean.

These books are not books of problems in the sense familiar to many of our teachers. The solutions of the problems are given very completely and there is little demand for effort on the part of the student. If one believes that the student learns faster by doing problems himself rather than by the study of complete solutions of problems by others, this characteristic will make the books unattractive.

The books are, rather, engineering texts in which the discussion of such problems as the performance of a steam turbine is clothed in numerical terms as well as algebraic symbols. A knowledge of fundamental principles is assumed; it is their application that is emphasized. The numerical accompaniment gives a sense of magnitudes and an air of familiarity and concreteness for those to whom symbols and mathematical language are strange and abstract. The statement in terms of problems to be answered helps to make the engineer feel at home. There may possibly be a field for this type of pedagogical approach in our own educational institutions.

A Convenient Electrical Micrometer and Its Use in Mechanical Measurements

By ROSS GUNN,[1] WASHINGTON, D. C.

A simple electrical micrometer of great mechanical and electrical stability has been developed. The electrical-current output from the micrometer is accurately proportional to the impressed mechanical displacement. The least count of typical micrometers using portable microammeters as indicators and employing no amplification is 5/1,000,000 in. Zero drift, hysteresis, temperature, and pressure variations have been reduced to less than 1 per cent. Special circuits are described which permit the indication of the sums, differences, ratios, or products of mechanical displacements and hence are useful in many mechanical measurements. The micrometer is also convenient for zero and low-frequency vibration studies.

ENGINEERS charged with the research, development, and test of mechanical equipment have been long handicapped in the analysis of their structures by the lack of sufficiently convenient methods for the measurement of such items as displacement, force, torque, and mechanical power. In striving for a direct and satisfactory solution to the difficult problems of mechanical measurement, it seems expedient to adapt as completely as possible, the well-developed science of electrical measurement to the new requirements. To bridge the gap between mechanical and electrical measurement, it is necessary to provide some simple means for converting small mechanical displacements into appropriate electrical quantities like current or voltage. Moreover, it is most essential that the electrical quantity be exactly proportional to the mechanical displacement and not be subject to leakage or other troubles which cause a variation of response with frequency. An electromechanical link, satisfying the imposed requirements, has been developed and since it measures small mechanical displacements, it has been called an electrical micrometer.

The tube element of this micrometer, which serves as the important connecting link between the mechanical quantity to be measured and the resulting electrical current or potential, is shown in Fig. 1. This tube in its simplest form, as shown in Fig. 2, consists of an evacuated glass envelope 29, in which is sealed a hot electron-emissive filament 1, and two insulated plates 3 and 5, mounted on a supporting rod 35. The supporting rod, with its electrodes and necessary electrical connections 7, is carried by an elastic diaphragm 25 suitably sealed to the glass envelope. A small rod 13, spot-welded to the outside of the diaphragm, serves to communicate motion to the insulated-plate assembly 3 and 5. It is clear that a displacement of the arm by a screw 15, for example, will change the relative spacing of the hot filament 1, and the two plates 3 and 5, one plate being moved farther away from the filament while the other is moved closer to it. This change in filament spacing modifies the internal electrical resistance of the tube in accordance with the well-known laws of electronics, and thus changes the current in the associated electrical circuits. The tube shown in Fig. 1 is one type of several that have been developed for the measurement of small mechanical or torsional displacements. The micrometer tubes are designed to have a high mechanical rigidity and a high natural period of oscillation. Even those tubes which are designed to be highly sensitive to exceedingly small forces have mechanical periods exceeding 500 cycles per second, and it is known that they will accurately follow impressed vibrations of a frequency exceeding 60 cycles per second.

The electrical-micrometer tubes just described are used in connection with special electrical circuits which permit the achievement of a high degree of linearity and electrical stability. It is a well-known fact of electronics that the plate resistance of a vaccum tube changes very rapidly with slight or accidental changes in the filament emission or plate potential. In order that these accidental variations may not appear on the electrical meter which measures the small mechanical displacement, an electrical bridge circuit is employed of the type shown in Fig. 2.

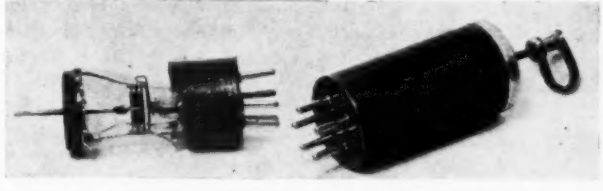

FIG. 1 THE TUBE ELEMENT OF THE ELECTRICAL MICROMETER. EXPLODED TUBE AT THE LEFT AND INTACT TUBE AT THE RIGHT

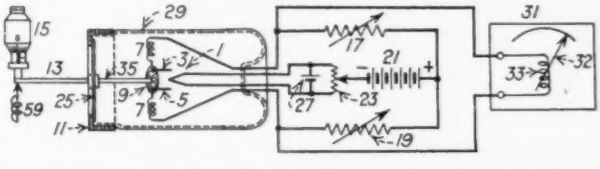

FIG. 2 CIRCUIT DIAGRAM OF THE TUBE FOR THE ELECTRICAL MICROMETER

A storage battery 21, or other source of electrical power which is reasonably stabilized by ballast tubes or other rough voltage-regulating device, supplies heating current to the electron-emissive cathode 1, and a potential of about 60 volts to the bridge circuit. The total power supplied to a typical micrometer tube is 5 watts. The electric current to the two plates 3 and 5, supplied through the highly flexible connections 7, traverses the variable resistances 17 and 19 in such a way that these resistances and the resistance between the filament and the plate 3, and the filament and the plate 5, make up the four arms of a typical bridge circuit. An electrical indicator 33 is connected across one diagonal of the bridge as shown.

The use of an electrical bridge circuit in the manner outlined accomplishes at least two highly desirable objectives. First, it reduces the electrical measurement to a comparison of two chang-

Presented at the Annual Meeting, Philadelphia, Pa., December 4–8, 1939, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until July 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

ing resistances, one of which increases while the other simultaneously decreases. Thus, changes in the filament emission or plate voltage do not affect the indicator to the first order. Such a system is electrically stable and the drift of the electrical zero is not troublesome. Second, the circuital arrangement leads to electrical currents in the indicator circuit which are directly proportional to the impressed mechanical displacement to a high degree of approximation. That is, the response curve is linear.

The underlying reasons for this fortunate state of affairs is readily made apparent by a brief study of the circuital relations and currents in an unbalanced bridge. In Fig. 2, suppose that the resistance between the cathode 1 and plate 3 is N, that between 1 and plate 5 is P, while the resistances of 17 and 19 are M and X, respectively. The electromotive force of the battery 21 is taken as E and its internal resistance as B, while the current in the indicator coil 33, having a resistance G, is represented by I. Under these circumstances, it may readily be shown[2] that the current I is given by

$$I = \frac{E\,(NX - MP)}{\left[B + \frac{(M+N)(X+P)}{M+N+X+P}\right]\left[G(M+N+X+P)+(N+P)(M+X)\right]} \quad \ldots\ldots\ldots\ldots [1]$$

The sensitivity of such a bridge circuit is a maximum when the resistances of all arms are the same so that in a typical case we may assume that the properties of the tube and the associated resistances are so adjusted that at exact balance $M = X = N = P = Q$ and therefore $I = 0$. Now let the plates of the micrometer tube be moved by some small outside mechanical displacement. This changes the resistance of both N and P to new values and a current I flows through coil 33 due to the unbalance. Let the values of resistances in this case be represented by

$$\left.\begin{aligned} M &= X = Q \\ N &= Q + \Delta N \\ P &= Q + \Delta P \end{aligned}\right\} \quad \ldots\ldots\ldots\ldots [2]$$

where ΔN and ΔP are the changes in resistance of N and P, respectively, due to the impressed mechanical displacement. Substituting these values in Equation [1], it may be shown that

$$I = \frac{E\,\Delta N}{\frac{BG}{Q}J + BK + \frac{G}{Q}L + \frac{LK}{J}} \quad \ldots\ldots\ldots [3]$$

where $J = 4Q + \Delta N + \Delta P$; $K = 4Q + 2(\Delta N + \Delta P)$; and $L = 4Q^2 + 2Q\,(\Delta N + \Delta P) + \Delta N \Delta P$. This expression reduces to

$$I = \frac{E\,\Delta N}{4Q^2\left(1 + \frac{\Delta N + \Delta P}{2Q}\right)} \quad \ldots\ldots\ldots\ldots [4]$$

if the battery resistance B and the indicator resistance G are both small compared to Q. This is usually the case and therefore since ΔN and ΔP are always small compared to Q, an essential proportionality always exists between the indicator current and the change in bridge resistance or the mechanical displacement of the tube arm 13.

In the exact expression of Equation [3], it is clear that if the second-order term $\Delta N \Delta P$ is kept small, the current (or voltage) output of the bridge I (or IG) is directly proportional to the change in resistance ΔN, if and provided

$$\Delta N + \Delta P = 0 \quad \ldots\ldots\ldots\ldots [5]$$

The foregoing results are of general application to bridge circuits and we proceed to apply them to our special system. The electric current i flowing between a hot cathode and a cold plate in a space-charge-limited vacuum tube is given[3] by

$$i = h\frac{\varphi^{3/2}}{X^2} \quad \ldots\ldots\ldots\ldots [6]$$

where h is a constant depending on the geometry of the tube, φ is the potential applied to the plate and X is the distance between the plate and filament. From Equation [6], we have that the internal resistances between plate and filament are

$$N = \frac{X^2}{h\varphi_N^{1/2}};\quad P = \frac{(d-X)^2}{h\varphi_P^{1/2}} \quad \ldots\ldots\ldots\ldots [7]$$

where d is the total effective separation of the two tube plates; whence

$$\Delta N = \frac{dN}{dX}\Delta X = \frac{2X}{h\varphi_N^{1/2}}\Delta X - \frac{X^2}{2h\varphi_N^{3/2}}\frac{d\varphi_N}{dX}\Delta X \quad \ldots\ldots [8]$$

$$\Delta P = \frac{dP}{dX}\Delta X = -\frac{2(d-X)}{h\varphi_P^{1/2}}\Delta X - \frac{(d-X)^2}{2h\varphi_P^{3/2}}\frac{d\varphi_P}{dX}\Delta X \quad \ldots\ldots [9]$$

therefore

$$\Delta N + \Delta P \doteqdot \left(\frac{4X}{h\varphi_Q^{1/2}} - \frac{2d}{h\varphi_Q^{1/2}}\right)\Delta X - 1/2\left[\frac{X^2}{h\varphi_N^{3/2}}\frac{d\varphi_N}{dX} + \frac{(d-X)^2}{h\varphi_P^{3/2}}\frac{d\varphi_P}{dX}\right]\Delta X \quad \ldots\ldots [10]$$

Since all arms of the bridge are adjusted to the same resistance $\varphi_N \doteqdot \varphi_P$ and $\frac{d\varphi_N}{dX} + \frac{d\varphi_P}{dX} \doteqdot 0$. Thus one sees that Equation [5] is satisfied for finite displacements when $X = d/2$ and this occurs when the filament is exactly centered between the plates in such a way that $N = P$. It is clear therefore that linearity may be established over any selected range by appropriate spacing of the two tube plates. Departures from linearity, even by 1 per cent, are not observed in actual micrometer tubes until ΔX approximates 10 per cent of the cathode-plate spacing. Thus, for all practical purposes the micrometer response relationship is linear.

In constructing the micrometer tube, the plates 3 and 5 are equally spaced from the filament 1 when the arm 13 is undeflected; therefore, the electrical resistance between the filament and each of these two plates is the same. In a typical tube this resistance approximates 10,000 ohms. Therefore, for maximum sensitivity and for a balance of the bridge such that the current in meter 33 is zero, one must adjust the two resistances 17 and 19 until they are approximately the same as the tube resistances. Under this condition of approximate balance, the reading of the meter 33 and hence the stability of the zero reading, is very insensitive to changes in the emission of filament 1, which are brought about by moderate changes in the filament power supply 27. Similarly, due to the balanced nature of the circuits employed, variations in the plate-battery supply 21, cause only second-order changes in the reading of the meter 33. These particular tube structures and special circuits are responsible for the electrical stability which may be attained with the new micrometer. The mechanical stability is also carefully maintained by rigidly mounting the mov-

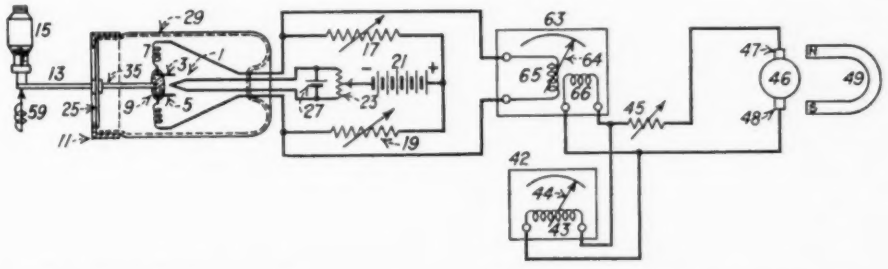

FIG. 4 CIRCUITS OF AN ELECTRICAL TACHOMETER, WATTMETER, AND THE ELECTRICAL MICROMETER COMBINED TO FORM A POWER-AND-TORSION METER FOR MEASURING MECHANICAL HORSEPOWER

ing parts and by the proper selection of material for the diaphragm 25, so that it exhibits vanishingly small mechanical hysteresis. The over-all stability of the device in practice has been found to be very good and will reproduce over periods of weeks to within less than 1 per cent of full scale, either for steady or oscillating mechanical deflections of the rod 13.

The sensitivity of typical micrometers approximates 150 microamperes per mil (0.001 in.) or about $^1/_2$ volt per mil when working into a high impedance. When used with standard rugged-type portable microammeters, the ratio of the meter pointer movement to the movement impressed on the arm 13 is about 10,000. The over-all stability of the device is unusually good if the power supply is reasonably constant, and one may expect the zero to drift less than 3 microamperes in the course of a day. Considerable attention has been devoted to the achievement of mechanical as well as electrical stability. The mechanical hysteresis is less than $^1/_2$ per cent of the maximum deflection even under adverse conditions.

FIG. 3 LIMIT AND TOLERANCE GAGE WHICH EMPLOYS THE ELECTRICAL-MICROMETER PRINCIPLE

Because of the inherent zero stability built into the tubes and associated circuits, this micrometer is especially suitable for the measurement or indication at a remote point of small displacements. These small displacements may originate as a result of tension, compression, or torsion in some stressed member; hence, if the member is elastic and obeys Hooke's law, the indicating electrical meter may be calibrated in terms of strain, stress, force, or torque. A small mass attached to the arm 13 of a micrometer tube converts it into an accelerometer which is readily calibrated in absolute units. By the employment of an elastic bellows, fluid pressures may be read. The device is an excellent scale for weights approximating a fraction of an ounce. By the use of a calibrated proving ring, its range may be expanded indefinitely. It has been applied with considerable satisfaction to limit and tolerance gages, such as shown in Fig. 3, and may be applied to the control of light cutting tools. The foregoing suggests only a few of the possible uses of the micrometer.

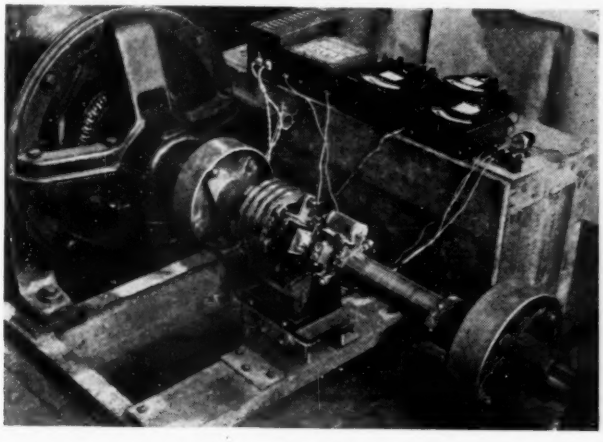

FIG. 5 POWER-AND-TORSION METER, THE CIRCUIT OF WHICH IS SHOWN IN FIG. 4

In the simplest type of application, the meter 33 may be an ordinary microammeter and in such a case mechanical displacements of the arm 13 as small as a wave length of blue light may be readily detected. In a similar way the meter 33 may be an oscillograph with amplifier and an instantaneous trace of the position of the arm 13 may be readily indicated both as to amplitude and wave form.

Clearly, the micrometer is useful for the analysis of low-frequency vibrations and a preliminary investigation in this field has been carried forward. It is found that the micrometer tubes will follow mechanical vibrations up to more than 65 cycles per second and reproduce the amplitude and wave form of the vibration on an oscillograph, at least to the limit of accuracy of measurement of the film. The author is of the opinion that the tubes at present available will follow vibrations accurately up to about 200 cycles per second, and by careful special design this can be raised to about 1000 cycles per second. Because the mi-

crometer can be made quantitatively to measure instantaneous, average, or root-mean-square values of a vibrator displacement, it is ideal for the study of surface finish.

Electrical meters of the wattmeter type are on the market which measure the value of the product of two electrical currents. Thus by the employment of two independent electrical micrometers, it is possible to measure the product of two mechanical displacements or the product of a mechanical displacement and an electrical potential such as that supplied by an electrical tachometer. Thus, it is possible to measure the product of speed and torque or mechanical horsepower. This is accomplished by mounting an electrical-micrometer tube on a drive shaft in such a way that the torsional strain in the shaft produces a mechanical displacement of the tube arm, which is proportional to the torque. The output from this electrical-micrometer tube is supplied to one coil 65 of a wattmeter type of electrical meter as shown in Fig. 4, while voltage from an electrical tachometer is supplied to coil 66. The electrical tachometer, consisting of a permanent magnet 49 and an armature 46 with brushes 47 and 48, provides a current which is proportional to the speed, while the electrical micrometer provides a current which is proportional to torque. Clearly the speed of the shaft may be measured by the current through the meter 43. Therefore, the wattmeter 64 may be calibrated directly in terms of mechanical power. Such a power-and-torsion meter has been built and has given good service. It is illustrated in Fig. 5. An improved model is being applied to the measurement of the mechanical power supplied to the propellers of a destroyer.

Special electrical meters are available on the market which measure the ratio of two electric currents. It is possible, therefore, to indicate on an electrical meter the over-all efficiency of a power plant. For example, the product of speed and torque by the use of a special circuit may be applied to one coil of a ratio meter while the rate at which fuel is supplied to the plant may be provided to the other coil through the agency of a suitable flowmeter employing an electrical micrometer. In such a setup the electrical meter will read the ratio of horsepower output to the rate of fuel supply and therefore can be calibrated directly in terms of over-all plant efficiency.

Because the field of electrical measurement is so well developed, it is possible to measure automatically by the use of this new micrometer almost any type of mechanical quantity. In addition to the quantities mentioned previously, it is possible, by the selection of appropriate electrical measuring devices already available, to measure the average or root-mean-square value of a varying mechanical displacement, its time derivative, its time integral, or the sum or difference of two independent displacements. It is even possible to indicate the value of one mechanical displacement raised to a power proportional to a second mechanical displacement. The electrical equipment is quite simple and even an oscillograph which will depict wave forms as well as the instantaneous values of a mechanical displacement is easy to use.

Space does not permit a detailed description of the applications already made of the new micrometer, but perhaps this article will serve to indicate its general usefulness and its applicability to the important problems of mechanical measurement. Because of the simplicity of the micrometer, its linearity, and its great stability, it has been a most convenient measuring device.

It is a pleasure to acknowledge the material assistance of Wayne C. Hall and Frank I. Louckes in the development and application of this micrometer.

The Influence of Hyperbolic Notches on the Transverse Flexure of Elastic Plates

By GEORGE H. LEE,[1] ITHACA, N. Y.

This paper[2] considers the solution of the two problems of the infinite plate, with two symmetrically disposed hyperbolic notches, subjected to (*a*) transverse bending and (*b*) twisting. The transverse-bending moments and torsional couples are so applied that the narrow section between the notches transmits the bending moment or the torsional couple. Using the Poisson-Kirchhoff theory, finite expressions were obtained for the deflection and stress in each problem.

THE two problems considered in this paper concern the infinite sheet with two symmetrically disposed hyperbolic notches. In the first problem the plate is transmitting a given total bending moment, as a beam of variable width but of constant thickness, under pure bending. In the second problem the plate is twisted, with OX as the axis of twist, Fig. 1*a*. The results of the two problems are shown graphically in Figs. 3 and 5. The stress concentration, i.e., the ratio of the stress occurring in the plate at the apex of the notch to the average stress over the narrow section between the notches, is plotted as a function of d/ρ where d is the length of the narrow section between the notches and ρ is the radius of curvature at the apex of the notch.

The deflections and stresses are found from the Poisson-Kirchhoff theory of the bending of thin elastic plates (1).[3] The differential equation for the transverse deflection w is $D\nabla^4 w = p$, where p is the pressure per unit area applied to the surface of the plate, and D is the flexural rigidity of the plate. In this instance, since the bending is due to edge loadings only, p is equal to zero; w is then a biharmonic function.

The sign convention and the stress resultants acting over sections normal to the middle plane are given in Fig. 1*b*. According to the Poisson-Kirchhoff theory, the stress resultants, in terms of the deflection w are

$$\left.\begin{aligned} G_x &= -D\left(\frac{\partial^2 w}{\partial x^2} + \nu\frac{\partial^2 w}{\partial y^2}\right) \\ G_y &= -D\left(\frac{\partial^2 w}{\partial y^2} + \nu\frac{\partial^2 w}{\partial x^2}\right) \\ H_x &= -H_y = (1-\nu)D\frac{\partial^2 w}{\partial x \partial y} \\ N_x &= -D\frac{\partial}{\partial x}\nabla^2 w \qquad N_y = -D\frac{\partial}{\partial y}\nabla^2 w \end{aligned}\right\} \quad \ldots\ldots\ldots [1]$$

where G_x, G_y are the transverse bending moments, N_x, N_y are the transverse shearing forces, and H_x, H_y are the torsional couples, all per unit length, acting over the sections x = constant and y = constant, respectively; ν is Poisson's ratio. The general conditions for each problem are as follows:

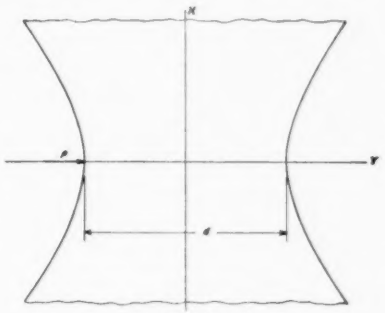

FIG. 1*a*

Bending. The plate must transmit a finite bending moment so that the integral of G over any cross section must yield a finite resultant, therefore, G itself must vanish at infinity. The deflection w must have symmetry with respect to both axes.

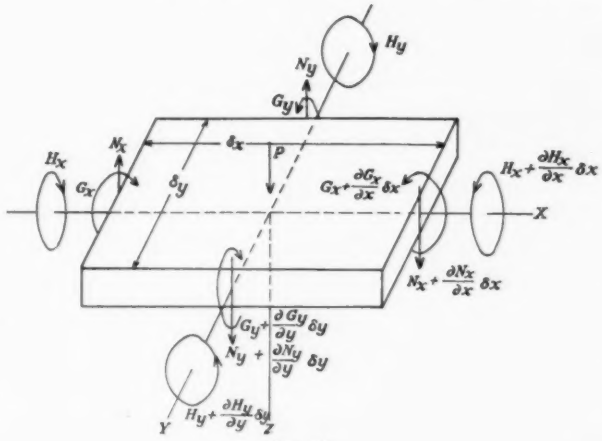

FIG. 1*b*

Torsion. The plate must transmit a finite torsional couple so that the integral of H over any cross section must yield a finite resultant and H itself must vanish at infinity. The deflection must be an odd function of x and of y.

In the orthogonal curvilinear coordinates defined by the conformal transformation $x + iy = f(u + iv)$, Equations [1] are transformed into the following, for actions over the sections v = constant

$$\left.\begin{aligned} J^4 G_v &= -D\left[J^2\left(\frac{\partial^2 w}{\partial v^2} + \nu\frac{\partial^2 w}{\partial u^2}\right) - \frac{1}{2}(1-\nu)\frac{\partial J^2}{\partial v}\frac{\partial w}{\partial v} + \frac{1}{2}(1-\nu)\frac{\partial J^2}{\partial u}\frac{\partial w}{\partial u}\right] \\ J^4 H_v &= (1-\nu)D\left[J^2\frac{\partial^2 w}{\partial u \partial v} - \frac{1}{2}\frac{\partial J^2}{\partial u}\frac{\partial w}{\partial v} - \frac{1}{2}\frac{\partial J^2}{\partial v}\frac{\partial w}{\partial u}\right] \\ J^3 N_v &= -D\left[J^2\frac{\partial}{\partial v} - \frac{\partial J^2}{\partial v}\right]\left[\frac{\partial^2 w}{\partial v^2} + \frac{\partial^2 w}{\partial u^2}\right] \end{aligned}\right\} \quad [2]$$

where J is the "stretch factor," and is given by the equation

$$J = \left[\left(\frac{\partial x}{\partial u}\right)^2 + \left(\frac{\partial y}{\partial u}\right)^2\right]^{1/2}$$

For actions over the sections u = constant, u and v are interchanged, except for H_u which is equal to $-H_v$.

The transformation used in the solution of these problems was of the form $x + iy = c \sinh (u + iv)$. From this we obtain the relations $x = c \cos v \sinh u$ and $y = c \sin v \cosh u$. The ranges for the variables u and v are $-\pi/2 < v < +\pi/2$ and $-\infty < u < +\infty$. For v a constant we obtain a family of hyperbolas and for u a constant a family of ellipses.

Over the free boundaries, i.e., the hyperbolas $v = \pm v_0$, the stress resultants must vanish. Kelvin and Tait (1) have pointed out that a distribution of torsional couples over a section is statically equivalent to a distribution of transverse shearing forces equal to $-\partial H/\partial s$ per unit length, where s is the tangent to the section. Then G_v and $N_v - \partial H_v/\partial s$ must both vanish over the free boundary $v = \pm v_0$. The sense of the tangent s is so chosen that together with the outward normal n and the z axis the three form a right-handed coordinate system. Goodier (2) has further modified the boundary conditions as follows: Since $N_v = -D \frac{\partial}{\partial n} \nabla^2 w$; w being biharmonic, $\nabla^2 w$ is harmonic and must possess a conjugate Ω such that $\frac{\partial}{\partial n} \nabla^2 w = \frac{\partial \Omega}{\partial s}$; the latter boundary condition may then be written $D \frac{\partial \Omega}{\partial s} + \frac{\partial H_v}{\partial s} = 0$ Integrating this with respect to the tangent, it follows that $D\Omega + H_v$ equals a constant over the free boundaries $v = \pm v_0$.

The Bending Problem

The solution was found, after examination of numerous simple biharmonic functions having the requisite symmetry, to be of the form[4]

$$w = Av \sin v \cosh u + B \cos v \cosh u + Eu \cos v \sinh u + F$$

In this case, Equation [2] takes the form of Equation [3] below:

$$J^4 G_v = -\frac{Dc^2}{4}\left[\{A[(1+\nu)\cos 3v + (5-\nu)\cos v] - 4B(1-\nu)\cos v + E[2\nu \cos 3v - (1-5\nu)\cos v]\} \cosh u + \{2A + E(1+\nu)\}\cos v \cosh 3u\right] \quad [3]$$

and $D\Omega + H_v$ takes the form

$$D\Omega + H_v = -\frac{Dc^2}{4J^4}\left[\{A[(3-\nu)\sin 3v - (7-3\nu)\sin v] + 4B(1-\nu)\sin v + E[2\sin 3v - (1+3\nu)\sin v]\} \sinh u + \{2A + E(1+\nu)\}\sin v \sinh 3u\right] \quad [4]$$

while the stretch factor J is given by

$$J^2 = \frac{c^2}{2}(\cos 2v + \cosh 2u)$$

Over the free boundary the coefficients of the variable terms of $D\Omega + H_v$ must vanish, while G_v must vanish identically. These conditions give rise to the following simultaneous equations

$$A[(1+\nu)\cos 3v_0 + (5-\nu)\cos v_0] - 4B(1-\nu)\cos v_0 + E[2\nu \cos 3v_0 - (1-5\nu)\cos v_0] = 0 \quad [5]$$

$$2A + E(1+\nu) = 0 \quad [6]$$

$$A[(3-\nu)\sin 3v_0 - (7-3\nu)\sin v_0] + 4B(1-\nu)\sin v_0 + E[2\sin 3v_0 - (1+3\nu)\sin v_0] = 0 \quad [7]$$

$$2A + E(1+\nu) = 0 \quad [8]$$

Solving these equations for B and E in terms of A

$$E = -\frac{2}{1+\nu}A \quad [9]$$

$$B = \frac{3+\nu+(1-\nu)\cos 2v_0}{2(1+\nu)}A \quad [10]$$

It is to be noted that Equations [6] and [8] are identical, and that Equations [5] and [7] are dependent. Imposing the condition that the deflection is zero at the origin ($u = v = 0$), the value of F is

$$F = -\frac{3+\nu+(1-\nu)\cos 2v_0}{2(1+\nu)}A \quad [11]$$

The integral of G_u over the section $u = 0$ ($x = 0$) is equal to the average bending moment per unit length G times the length of the section. This yields the value of A in terms of G

$$A = \frac{1+\nu}{1-\nu}\frac{2Gc^2 \sin v_0}{D\{2(3+\nu)v_0 - (1-\nu)\sin 2v_0\}} \quad [12]$$

The stress resultants then become

$$G_u = \frac{-2G \sin v_0}{(\cos 2v + \cosh 2u)^2[2(3+\nu)v_0 - (1-\nu)\sin 2v_0]}\left[\{-(3+\nu)\cos 3v + [-(5+3\nu) + 2(1-\nu)\cos 2v_0]\cos v\}\cosh u - 2(1+\nu)\cos v \cosh 3u\right] \quad [13]$$

$$G_v = \frac{2(1-\nu)G \sin v_0[(2\cos 2v_0 - 1)\cos v - \cos 3v]\cosh u}{(\cos 2v + \cosh 2u)^2[2(3+\nu)v_0 - (1-\nu)\sin 2v_0]} \quad [14]$$

$$H_u = -H_v = \frac{2G \sin v_0[\{(1+\nu)\sin 3v - [3+\nu-2(1-\nu)\cos 2v_0]\sin v\}\sinh u + 2\sin v \sinh 3u]}{(\cos 2v + \cosh 2u)^2[2(3+\nu)v_0 - (1-\nu)\sin 2v_0]} \quad [15]$$

$$N_u = \frac{8\sqrt{2}\,G \sin^2 v_0[(\cos 3v - 4\cos v)\sinh u - \cos v \sinh 3u]}{d[2(3+\nu)v_0 - (1-\nu)\sin 2v_0](\cos 2v + \cosh 2u)^{3/2}} \quad [16]$$

$$N_v = \frac{8\sqrt{2}\,G \sin^2 v_0[(\sin 3v + 2\sin v)\cosh u - \sin v \cosh 3u]}{d[2(3+\nu)v_0 - (1-\nu)\sin 2v_0](\cos 2v + \cosh 2u)^{3/2}} \quad [17]$$

The deflection of the plate is

$$w = \frac{1+\nu}{1-\nu}\frac{Gd^2}{2D \sin v_0[2(3+\nu)v_0 - (1-\nu)\sin 2v_0]}\left[v \sin v \cosh u + \frac{3+\nu+(1-\nu)\cos 2v_0}{2(1+\nu)}(\cos v \cosh u - 1) - \frac{2}{1+\nu}u \cos v \sinh u\right] \quad [18]$$

In Fig. 2 are plotted G_u, G_v, and H_u in terms of G, over the section $u = 0$ and the free boundary $v = \pm v_0$. The maximum G_u occurs at the apex of the notch and is large in comparison to the maxima of the other stress resultants occurring in the plate

[4] The possibility of solving these problems in this manner was suggested by Neuber's solutions of the corresponding problems of plane stress.

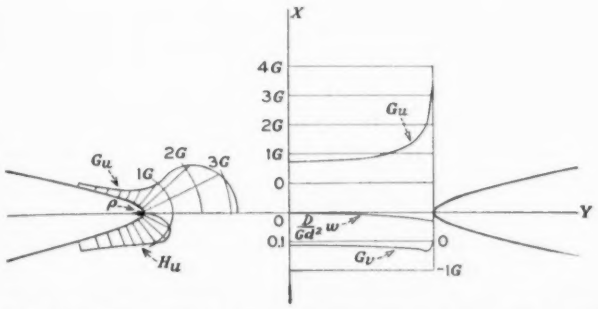

FIG. 2 DISTRIBUTION OF STRESS RESULTANTS IN A NOTCHED PLATE UNDER TRANSVERSE BENDING; $d/\rho = 64.6$

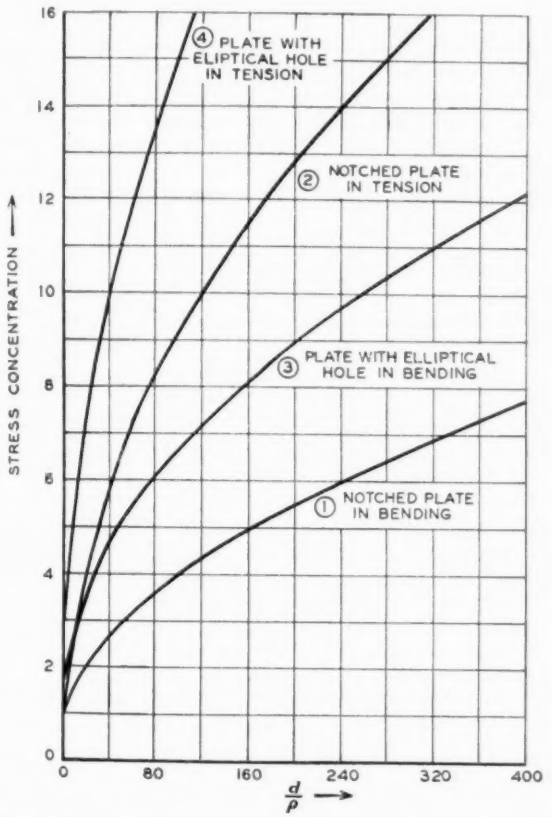

FIG. 3 STRESS CONCENTRATION PLOTTED AS A FUNCTION OF d/ρ

G_u is then the stress resultant that is the governing factor in determining the stress concentration. The ratio G_u/G is plotted against d/ρ, where d is the length of the narrow section between the notches, shown in Fig. 1*a*, and ρ is the radius of curvature of the notch at its apex; for comparison the stress concentration for the notched plate under tension (3) is plotted against d/ρ as curve 2 in Fig. 3. Curves 3 and 4 in Fig. 3 are the stress concentrations for the closely allied problems of the elastic plate with an elliptical hole, major axis parallel to the y axis, subjected to bending (2) and tension (3), respectively. For these latter two curves, the stress concentration is plotted against d/ρ, where d is here the length of the major axis and ρ is the radius of curvature of the ellipse at the end of the major axis. Values of $(D/Gd^2)w$ are plotted along the y axis in Fig. 2.

As a check on the validity of the solution obtained, the deflection should approach that of a strip of uniform width as the notches become very flat, i.e., as $v_0 \to 0$. The region considered must be that for small u; near the axis $u = 0$ the change in section is of secondary importance, but removed from this region, the change in section becomes of prime importance unless $v_0 = 0$, a case for which the present results are not directly applicable. For small u, $\sinh u \approx u \approx x$, $\cosh u \approx 1 + x^2/2$, and $\sin v \approx v \approx y$. Substituting these into the expression for the deflection, we obtain

$$w \to \frac{-G}{2EI}(x^2 - \nu y^2)$$

It will be observed that this limit represents the bending of a strip on the assumption that anticlastic curvature is free to occur. It is well known however that when a strip is appreciably bent, the anticlastic curvature does not develop. The section remains flat, except for a slight curling at the edge. The solution customarily adopted supposes that bending moments are called into play, on sections parallel to the edges of the strip, sufficient to prevent the anticlastic curvature. Near the edge there is a local transition to the edge condition of freedom from stress.

The question arises as to whether the solution for the notched plate should not be such as to give a limiting form for the parallel strip in which the anticlastic curvature does not appear.

The answer appears to be that the solution as given will represent the initial stage of bending, in which no appreciable mean stress develops. For, as appears from Lamb's solution (4, 5) the prevention of anticlastic curvature in the strip is associated with the development of mean stress in the edge zones, and so will not occur in the initial stage.

Since the concentration of stress is localized around the apex of the notch, it is reasonable to expect that the solution will apply with fair approximation to notches in strips of finite width. The corresponding expectations in the case of plane stress have been borne out by the photoelastic measurements of Frocht (6), the calculations having been made by Neuber (3).

THE TORSION PROBLEM

The solution of this problem was found to be of the form

$$w = Av\cos v\sinh u + B\sin v\sinh u + Eu\sin v\cosh u$$

The conditions that G_v and $D\Omega + H_v$ must vanish and equal a constant over a free boundary, respectively, yield the following simultaneous equations

$$[A(3-\nu) - 2E]\cos 3v_0 + [A(7-3\nu) + 4B(1-\nu) - E(1+3\nu)]\cos v_0 = 0 \quad [19]$$

$$2A - E(1+\nu) = 0 \quad [20]$$

$$[-A(1+\nu) + 2E\nu]\sin 3v_0 + [A(5-\nu) + 4B(1-\nu) + E(1-5\nu)]\sin v_0 = 0 \quad [21]$$

$$2A - E(1+\nu) = 0 \quad [22]$$

Solving these equations for B and E in terms of A, we obtain

$$E = \frac{2}{1+\nu}A \quad [23]$$

$$B = \frac{3+\nu-(1-\nu)\cos 2v_0}{2(1+\nu)}A \quad [24]$$

The constant A is evaluated in the same manner as in the first problem: The integral of H_u over the section $u = 0$ is equal to the average torsional couple per unit length H times the length of the section d. The value of A thus obtained is

$$A = \frac{1+\nu}{1-\nu}\,\frac{Hd^2}{2D\sin v_0[2(1+\nu)v_0+\{7+\nu-(1-\nu)\cos 2v_0\}\tan v_0]} \quad [25]$$

The stress resultants are then

$$G_u = \frac{-2H\sin v_0}{[2(1+\nu)v_0+\{7+\nu-(1-\nu)\cos 2v_0\}\tan v_0](\cos 2v+\cosh 2u)^2}$$
$$[\{(3+\nu)\sin 3v+[-(17+7\nu)+2(1-\nu)\cos 2v_0]\sin v\}\sinh u + 2\sin v\sinh 3u] \quad [26]$$

$$G_v = \frac{-4H\sin v_0[-(1-\nu)\sin 3v+\{2(5+\nu)-(1-\nu)\cos 2v_0\}\sin v]\sinh u}{[2(1+\nu)v_0+\{7+\nu-(1-\nu)\cos 2v_0\}\tan v_0](\cos 2v+\cosh 2u)^2} \quad [27]$$

$$H_u = -H_v = \frac{2H\sin v_0}{[2(1+\nu)v_0+\{7+\nu-(1-\nu)\cos 2v_0\}\tan v_0](\cos 2v+\cosh 2u)^2}$$
$$[\{(1+\nu)\cos 3v+[5(3+\nu)-2(1-\nu)\cos 2v_0]\cos v\}\cosh u + 2\cos v\cosh 3u] \quad [28]$$

$$N_u = \frac{8\sqrt{2}\,H\sin^2 v_0[(\sin 3v+2\sin v)\cosh u-\sin v\cosh 3u]}{d[2(1+\nu)v_0+\{7+\nu-(1-\nu)\cos 2v_0\}\tan v_0](\cos 2v+\cosh 2u)^{5/2}} \quad [29]$$

$$N_v = \frac{8\sqrt{2}\,H\sin^2 v_0[(2\cos v-\cos 3v)\sinh u+\cos v\sinh 3u]}{d[2(1+\nu)v_0+\{7+\nu-(1-\nu)\cos 2v_0\}\tan v_0](\cos 2v+\cosh 2u)^{5/2}} \quad [30]$$

and the deflection is

$$w = \frac{1+\nu}{1-\nu}\,\frac{Hd^2}{2D\sin^2 v_0[2(1+\nu)v_0+\{7+\nu-(1-\nu)\cos 2v\}\tan v_0]}$$
$$\left[v\cos v\sinh u+\frac{3+\nu-(1-\nu)\cos 2v_0}{2(1+\nu)}\sin v\sinh u + \frac{2}{1+\nu}u\sin v\cosh u\right] \quad [31]$$

In Fig. 4 is plotted H_u and G_u, in terms of H, over the section $u = 0$ and the free boundaries $v = \pm v_0$. It may be expected,

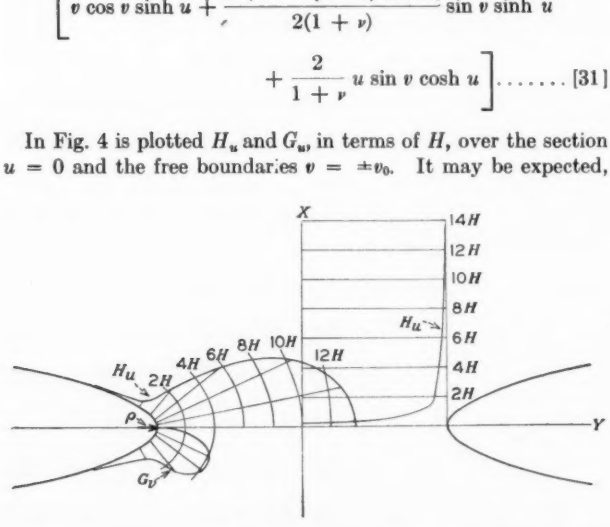

FIG. 4 DISTRIBUTION OF STRESS RESULTANTS IN A NOTCHED PLATE IN TORSION; $d/\rho = 27.8$

as in the bending problem, that these results for the infinite sheet may be applied with fair approximation to notches in strips of finite width. It will be observed that the stress concentration, H_u/H plotted against d/ρ for the present problem, shown in Fig. 5, is considerably higher than G_u/G for the bending problem. As a check on the results of this problem, the expression for the deflection should approach that for the strip of uniform width, as $v_0 \to 0$. For small u and as $v_0 \to 0$, the expression for the deflection approaches the form:

$$w \to \frac{H}{D(1-\nu)}\,xy$$

which is the deflection of the strip of uniform width subjected to torsional couples.

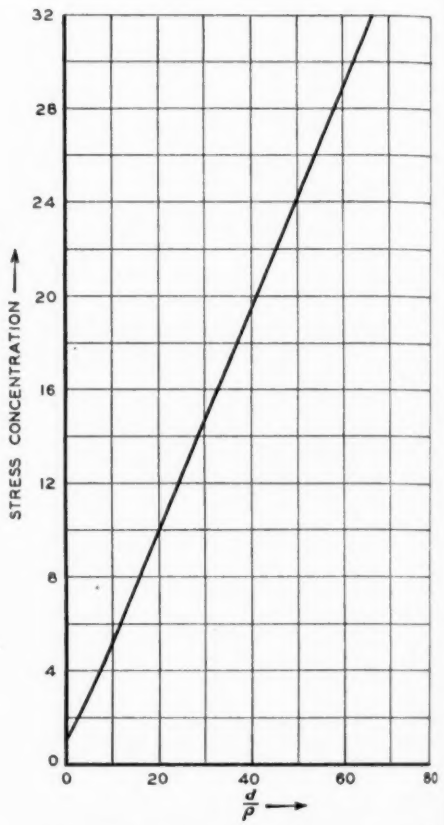

FIG. 5 STRESS CONCENTRATION PLOTTED AS A FUNCTION OF d/ρ FOR THE NOTCHED PLATE IN TORSION

ACKNOWLEDGMENT

The author wishes to express his appreciation to Prof. J. N. Goodier of Cornell University for the suggestion of the problems and his aid in their solution.

A Photoelastic Study of Stresses in Rotating Disks

By R. E. NEWTON,[1] ST. LOUIS, MO.

The recent experiments of Hetényi and others in developing a technique for "freezing" stresses in bakelite and other photoelastic plastics have broadened tremendously the scope of the photoelastic method of stress analysis. In addition to making possible the solution of three-dimensional problems, the new technique offers itself as a powerful tool in solving problems in which it is inconvenient to study the fringe pattern while the model is actually under load. Problems of centrifugal stresses in constant-speed rotors fall in this class and are readily handled by the stress-freezing method. It is the purpose of this paper to discuss the application of the technique to the determination of the stresses in rotating disks of uniform thickness having symmetrically placed noncentral holes, as shown in Fig. 1 (1, 2).[2]

WE FIRST review the essential phenomenon and theory of the "stress freezing" technique (3). As the models used in the present investigation were made of bakelite BT 61-893, the effect will be described with particular reference to this plastic. The annealing characteristics of bakelite are explained on the assumption that it consists of two principal phases. One of these phases, the A phase, is readily fusible at low temperatures and the other, the C phase, fuses only at quite high temperatures. As the temperature rises, the viscosity of the A phase is rapidly lowered until at about 230 F this phase no longer has appreciable strength. If a load were now applied to the bakelite it would be carried entirely by the remaining three-dimensional lattice—the C phase. Under these conditions the deformation produced by a given load will be about 640 times that which would occur at room temperature. The corresponding photoelastic effect is about 26 times as great as at room temperature. When the temperature is lowered while the bakelite is still under load, the A phase solidifies, filling the interstices of the space lattice formed by the C phase. Then, when the load is removed, the specimen will remain deformed and continue to exhibit substantially the same photoelastic fringe pattern that was produced at the higher temperature under load; however, the specimen actually recovers an amount which is equal to $^1/_{640}$ of the original deformation and the optical effect is reduced by $^1/_{26}$.

Taking advantage of this phenomenon, it is possible to spin a bakelite model of a rotor at constant speed, raise the temperature to 230 F, cool slowly, then stop the rotation, remove the model from the mounting, and examine the resultant photoelastic pattern at leisure. This method avoids the difficulties of a stroboscopic study and makes possible photoelastic investigations of a class of problems of great importance in engineering design. The present problem illustrates these possibilities.

The models used were made of bakelite BT 61-893, as noted previously. The diameter of the model was limited by the size of plate available and the dimensions finally selected, as shown in Fig. 1, were: Outside diameter, $2b = 5.45$ in.; radius of circle containing centers of holes, $a = 1.00$ in.; spacing of holes, 60 deg; diameter of holes, $d = 0.250$ and 0.375 in. for model sets A and B, respectively. Since the speed of rotation was limited by practical considerations to 1800 rpm, it was deemed advisable to use a model thickness of approximately 1 in. to secure a sufficiently high order of isochromatic fringe (about the 9th) at the points of maximum stress. Polished plates of bakelite were not available in thicknesses greater than $^1/_2$ in.; therefore, it was necessary to use two identical models of this thickness and subsequently to examine them together in the polariscope so that the optical effect would be double that secured with one model.

Oversized disks were first cut out of the bakelite plate with a coping saw. The holes were drilled in the disks using a steel faceplate shown in Fig. 2 as a drill guide. The disks were then bolted together to the faceplate and turned to the proper outside diameter.

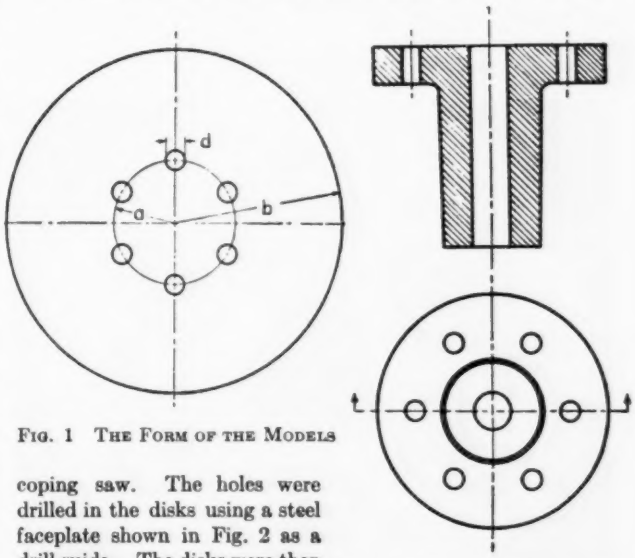

FIG. 1 THE FORM OF THE MODELS

FIG. 2 THE FACEPLATE USED FOR DRILLING AND SPINNING THE MODELS

The mounting system was devised with the dual purpose of keeping the disks accurately centered during annealing and offering a minimum of constraint to their deformation. Since it was not possible to eliminate all constraint, a compromise was made, partially constraining the model by the use of supporting bolts in three of the holes at 120-deg intervals and allowing the other three holes to be entirely free. The faceplate shown in Fig. 2 was used to hold the bolts. To reduce the constraint at the three bolts it was decided to use undersized bolts and surround them with rubber bushings. The use of undersized bolts gave the further advantage that centering could be done by shifting the bolts slightly in the holes of the faceplate. Accurate center-

Presented at the Annual Meeting, Philadelphia, Pa., December 4–8, 1939, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until July 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

ing was effected by using a dial micrometer to test eccentricity; small errors were corrected by tapping the bolts. A section detail of the method of mounting the models on the bolt is shown in Fig. 3. Rotation was produced by a synchronous motor on whose shaft the faceplate made a tight friction fit.

An oven heated electrically was built around the models and

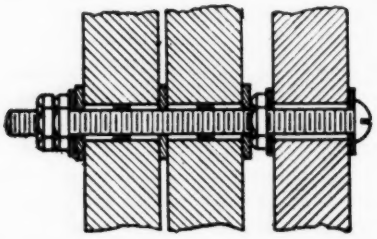

FIG. 3 UNDERSIZE BOLTS FITTED WITH RUBBER BUSHINGS WERE USED TO MOUNT THE DISKS ON THE FACEPLATE FOR SPINNING DURING ANNEALING

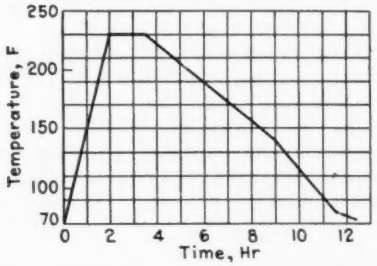

FIG. 4 TEMPERATURE CYCLE FOR ANNEALING THE MODELS

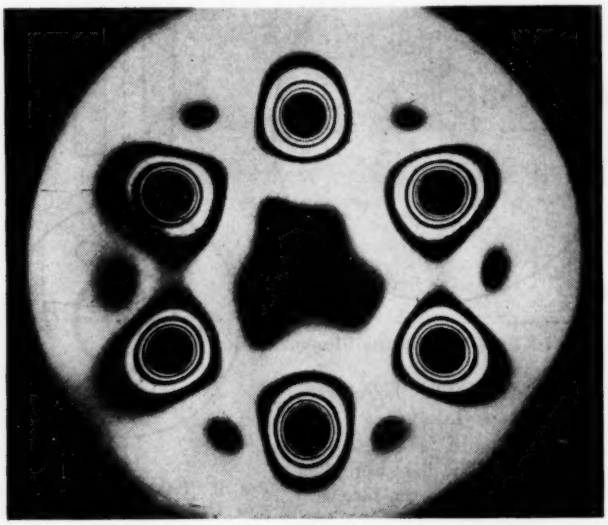

FIG. 5 FRINGE PATTERN OF MODEL *A*, ONE DISK

their mounting, the motor shaft projecting through the oven's side. Immediately after machining, the models were mounted, set in rotation, and the temperature varied in the manner shown in Fig. 4. Upon return to room temperature the models were removed from the oven, demounted, and photographed in the various desired combinations. Like tests were made upon model sets *A* and *B*.

Figs. 5 to 8, inclusive, show the successive stages in the development of the isochromatic fringe pattern for model *A*. The pictures show the fringe pattern corresponding to relative rotative speeds of 1, $\sqrt{2}$, $\sqrt{3}$, and 2, respectively. Actually they were not

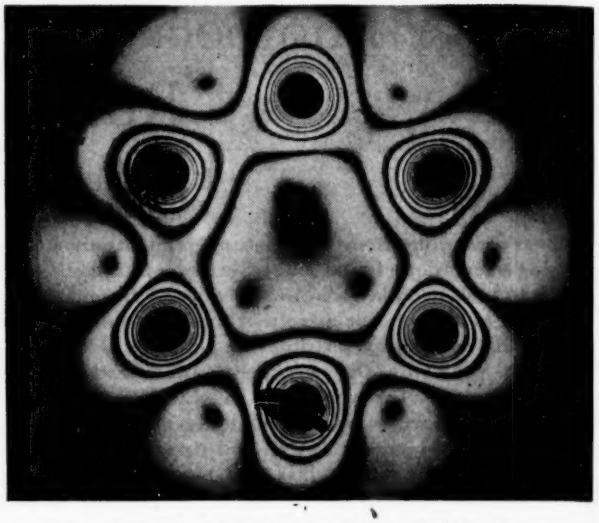

FIG. 6 FRINGE PATTERN OF MODEL *A*, TWO DISKS

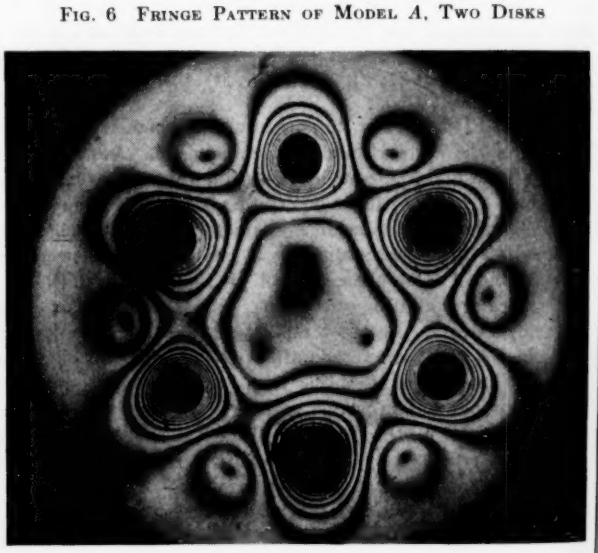

FIG. 7 FRINGE PATTERN OF MODEL *A*, THREE DISKS

FIG. 8 FRINGE PATTERN OF MODEL *A*, FOUR DISKS

obtained by varying the speed of a single model, but by superposing, successively, one, two, three, and four identical disks having the form of model *A*. Isochromatic lines appear first at the points of maximum stress which lie on the edge of each hole, approximately where the lines joining the center of the hole to the centers of the adjacent holes intersect the edge. Beginning as points, the fringes quickly become crescents and then form ovals encircling the holes. Further increase of speed causes the ovals to swell until they meet between the holes and snap apart to form a hexagon in the central portion of the disk and a rosette outside the holes. Shortly thereafter the rosette breaks at points radially beyond the holes and snaps into closed loops around the six outer isotropic points which lie between the holes a short distance beyond the circle of centers. There is also an isotropic point at the center and one radially inward from each of the free holes (the hole at the top of each picture was free). A study of the development of the isochromatic pattern in this manner overcomes one of the characteristic disadvantages of the stress-freezing method which ordinarily does not permit observing the formation of the pattern.

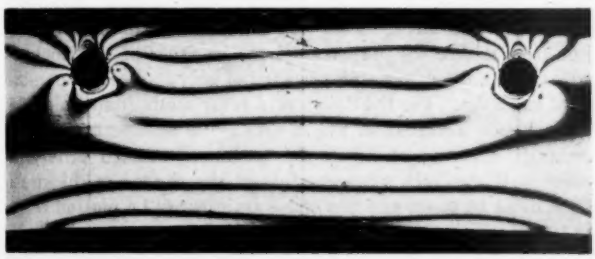

FIG. 9 FRINGE PATTERN OF A BEAM IN PURE BENDING

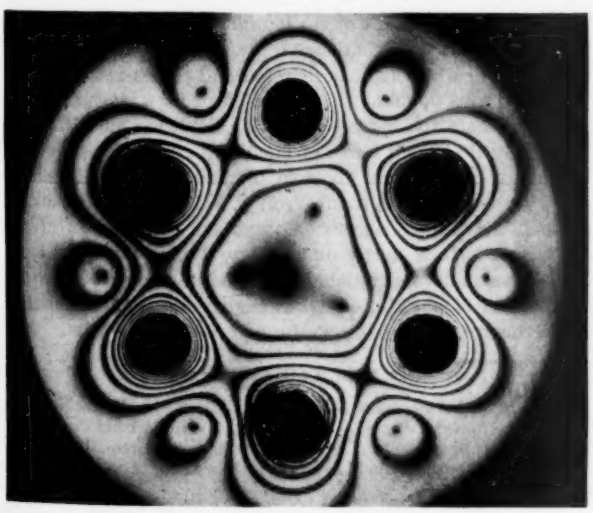

FIG. 10 FRINGE PATTERN OF MODEL *B*, TWO DISKS

Close examination discloses that the patterns around the free holes and those around the holes which held the model do not differ greatly. One may, using Saint Venant's principle, confidently apply the results obtained from a study of the patterns around the free holes without fear that the constraint of the mounting has appreciably affected these results.

An auxiliary test of a beam in pure bending was made to determine the principal stress difference represented by the first-order isochromatic fringe. A beam was made from the same plate as the models and subjected to the same annealing cycle while loaded by a pair of couples of known magnitude. Fig. 9 shows the residual fringe pattern. From elementary theory of strength of materials the stress-optic constant was computed to be 3.73 lb per sq in. per in. per fringe.

Because of the difficulty of accurately lining up four disks, the pattern of two disks, shown in Fig. 6, was used for the quantitative determination of the maximum stress. A similar pattern for model *B* is shown in Fig. 10. The maximum order of line appearing around the three free holes was determined from the original photographic plates by use of a magnifier. It was found to be 9.0 and 9.7 for models *A* and *B*, respectively. The total thickness of the model in each case was 1.046 in., so that the corresponding stresses were 32.2 and 34.6 lb per sq in., respectively.

The effect of increasing the size of hole is to increase markedly the maximum shear stress (shown by the order of the isochromatic fringe) throughout the parts of the disk away from the holes (compare Figs. 6 and 10), whereas the stress around the holes increases only slightly.

APPROXIMATE THEORY

In order to provide some basis for comparison of the photoelastic results with theory, an approximate theoretical solution was constructed. The starting point was the assumption that the thickness of the disk was sufficiently small compared with its diameter that a plane state of stress might be expected. Such a hypothesis is justified by a study of the exact solutions available for a disk of uniform thickness (4) and a disk having the form of a flat ellipsoid of revolution (5). On the basis of this assumption Timoshenko (6) gives the following solution for a solid disk of uniform thickness

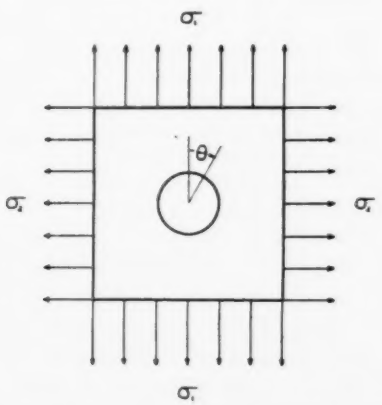

FIG. 11 A BODY, WITH A HOLE IN THE TENSION FIELD, SUBJECTED TO UNIFORM TENSIONS AT RIGHT ANGLES TO EACH OTHER

$$\left.\begin{aligned} \sigma_r &= \frac{3+\nu}{8}\rho\omega^2(b^2-r^2) \\ \sigma_t &= \frac{3+\nu}{8}\rho\omega^2 b^2 - \frac{1+3\nu}{8}\rho\omega^2 r^2 \end{aligned}\right\} \quad \ldots\ldots\ldots [1]$$

where σ_r and σ_t are, respectively, the radial and tangential stresses; ν is Poisson's ratio; ρ is the density of the disk; ω is the angular velocity; b is the radius of the disk; and r is the distance from the center to the point under consideration.

In order to estimate the effect of a hole not at the center we consider a body subjected to uniform tensions σ_1 and σ_2 at right angles, as shown in Fig. 11. If we designate the tangential stress at the edge of the hole by σ, we may compute σ by superposing the results for an infinite plate with a hole under tension and the results for the same plate with the tension at right angles to the first (7). This gives

$$\sigma = \sigma_1 (1 - 2\cos 2\theta) + \sigma_2 \left[1 - 2\cos 2\left(\theta - \frac{\pi}{2}\right)\right]$$

$$= \sigma_1 + \sigma_2 - 2(\sigma_1 - \sigma_2)\cos 2\theta \ldots\ldots\ldots\ldots [2]$$

If we assume that $\sigma_1 > \sigma_2$ and designate the maximum value of σ by σ_m putting $\theta = \pm(\pi/2)$, we obtain

$$\sigma_m = 3\sigma_1 - \sigma_2 \ldots\ldots\ldots\ldots\ldots\ldots [3]$$

We may now obtain an approximate solution for the maximum stress on the periphery of a noncentral hole by neglecting the variation of the tangential and radial stresses in the neighborhood of the hole and replacing σ_1 and σ_2 in Equation [3] by σ_t and σ_r, respectively, from Equation [1]. If the center of the hole is at a distance a from the center of the disk, we have

$$\sigma_m = 3\sigma_t - \sigma_r = \rho\omega^2 \left\{ [(3 + \nu)/4]\, b^2 - \nu a^2 \right\} \ldots\ldots [4]$$

Comparing this result with Equations [1] we see that we shall expect the maximum stress to be found at either the inner or outer edge of the holes. The magnitude of the stress computed by Equation [4] is 27.6 lb per sq in. As noted previously, the maximum stress actually occurs at points on the edges of the holes about 60 deg from the innermost points and has the magnitude 32.2 and 34.6 lb per sq in. for models A and B, respectively. We may explain the quantitative discrepancy by noting that the stress should be greater than that predicted by Equation [4] because the holes reduce the net cross section of the disk around the circle of centers.

We may attempt, in a naïve way, to take account of the effect of this reduction of cross-sectional area by multiplying the value of the maximum stress given by Equation [4] by the ratio of the cross-sectional area along the circle of centers before drilling the holes to the area after drilling. This gives

$$\sigma_m = \rho\omega^2 \left[\frac{3 + \nu}{4} b^2 - \nu a^2 \right] \left(\frac{2\pi a}{2\pi a - 6d} \right) \ldots\ldots [4a]$$

The assumption here is that the form of the stress distribution is unaltered by the reduction of area but that the maximum stresses are in the inverse ratio of the areas. This is clearly not the case and we should expect the stress to redistribute itself in such a way that the maximum value would be less than that predicted by Equation [4a]. Actually this effect occurs and the stresses of 36.3 and 43.0 lb per sq in. for models A and B, respectively, computed by Equation [4a] are higher than the actual stresses.

The appearance of the isotropic points is easily understood. The one at the center needs no comment. In an unpierced disk the tangential stress exceeds the radial stress everywhere except at the center, where they are equal, as seen from Equations [1]. The effect of the holes is to increase both the tangential and radial stress near the holes. Since, however, the isotropic points are ones at which the radial and tangential stresses are equal, it follows that the increase of the radial stress is the greater and this results in the appearance of isotropic points not at the center. The nonappearance of isotropic points radially inward from the holes in which the disks were supported is explained by the fact that the deformation of the disks causes the rubber bushings of the mounting to exert an inward radial pressure at these holes. The effect of this compression was to reduce the radial tension below the tangential-tension value.

Inspection of Equations [1] and [4] shows that the stress distribution depends upon the value of Poisson's ratio. For materials commonly used in rotor construction this value ranges between 0.25 and 0.30. In bakelite at 230 F it is 0.50. This large difference fortunately affects the maximum stress but little. Computing the maximum stress from Equation [4], we find that the value obtained differs by less than 4 per cent when the extreme values 0.25 and 0.50 are used. It is further reassuring to note that the stress in the bakelite will be greater than that in the corresponding metal rotor so that a design based on photoelastic data will certainly be safe. A rather thorough investigation of the effect of the value of Poisson's ratio upon the stress distribution by Coker and Filon (8) also led to the conclusion that the error introduced could safely be neglected.

Conclusions—Acknowledgments

The technique utilized in this problem is applicable to a great variety of other problems involving centrifugal stress. Problems in which gravitational body forces are replaced by centrifugal forces have already been attacked stroboscopically (9). They can now be handled with greater facility by stress freezing. This technique obviates use of elaborate loading devices necessitated by the requirement that photoelastic specimens be observed under load. Hetényi has discussed its applicability to problems of three-dimensional stress (3).

Certain refinements of technique suggest themselves for subsequent experiments. In the present investigation, although the maximum shearing stress was determined throughout the rotor (this is directly proportional to the order of the isochromatic fringe), the direct stress was found only at the free boundaries of the holes. For the design of a rotor made from a ductile material such information would usually be sufficient since the maximum shearing stress is the customary design criterion. However, if auxiliary measurements of the change in thickness of the disks be made and the stress trajectories be plotted from the isoclinic lines, it would be possible to determine completely the state of stress throughout the rotor (2). Because of the small value of the modulus of elasticity (E = 1070 lb per sq in.) and the large value of Poisson's ratio (ν = 0.50) at the elevated temperature, the amount of the lateral deformation is large and easily measured with satisfactory accuracy. The use of a polariscope in which light is reflected and passes twice through the model, thus doubling the optical effect for a given thickness would eliminate the necessity of using duplicate models. It is quite likely that other forms of mounting can be devised which will permit even greater freedom of movement of the model.

The author wishes to thank Prof. F. W. Bubb for his encouragement, his helpful suggestions, and for his criticism of the manuscript. He is deeply indebted to E. H. Sager for innumerable valuable suggestions. He wishes also to thank the departments of physics, electrical engineering, and mechanical engineering for the use of apparatus and research facilities.

A Rational Definition of Yield Strength

By W. R. OSGOOD,[1] WASHINGTON, D. C.

Explicitly or implicitly the yield strength of a material is often used as a measure of incipient structural damage. With the yield strength determined by conventional methods, however, it cannot be said in general for two structural elements geometrically alike but of different materials that similar loads, producing maximum stresses equal to the yield strengths in the two cases, are simply related to the yield strengths. A definition of yield strength is proposed in this paper which often has the advantage that, for geometrically similar structures of different materials, loads producing maximum stresses equal to the yield strength are proportional to the yield strength.

IT IS generally recognized that most definitions of yield strength are arbitrary. Except in the case of the simplest stress-strain diagram composed of two straight lines, the modulus line and a horizontal (approximated in mild steel), the commonly used definitions of yield strength or yield point have limited physical significance. This difficulty is likely to inhere in any definition of yield strength, but there is an objection to most definitions which can be avoided or mitigated in many cases. When the yield strength is used as a measure of maximum allowable deformation of a structural element, no simple relation exists in general between the damaging deformations obtained with two materials having different stress-strain curves, except under conditions of pure tension or compression. Where it is a question of failure by instability in the plastic range, no simple relation exists in general between the critical loads obtained with two such materials. By defining suitably the yield strength, however, simple relations may be found between the damaging deformations or between the critical loads. These statements become clear as to deformation when, for example, bending is considered.

Suppose that a section of a straight beam is subjected to a bending moment M such that, in the extreme tensile fiber, a yield strength S_1 is just reached. Then from Fig. 1 we may write

$$M = \int_{-c_2}^{c_1} sybdy$$

Since $y = \dfrac{he}{e_1 - e_2}$, this equation may be written

$$M = \frac{h^2}{(e_1 - e_2)^2} \int_{e_2}^{e_1} bsede$$

where e is the strain in the fiber at the distance y from the neutral axis, and e_1 and e_2 are the strains in the extreme tensile and compressive fibers, respectively. Now consider a second beam of the same cross-sectional dimensions but of different material subjected to a moment M' which produces a tensile extreme fiber stress equal to the yield strength S_1' of this material. The relation between bending moment and extreme fiber strains e_1' and e_2' for this beam is

$$M' = \frac{h^2}{(e_1' - e_2')^2} \int_{e_2'}^{e_1'} bs'e'de'$$

The two moments M and M' will be simply related only if a simple relation exists between the stress-strain curves of the materials. If the two stress-strain curves are affinely related, that is, the one curve could be got from the other by the transformation

$$e' = \alpha e \qquad s' = \beta s \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

where α and β are constants, then we should have for the second beam

$$M' = \frac{h^2}{\alpha^2(e_1 - e_2)^2} \int_{e_2}^{e_1} b\beta s\alpha^2 ede$$

$$= \frac{\beta h^2}{(e_1 - e_2)^2} \int_{e_2}^{e_1} bsede$$

or

$$M' = \beta M \ldots\ldots\ldots\ldots\ldots\ldots [2]$$

the simplest possible relation between the two bending moments. It is seen from Equation [1] that with S_1 the yield strength of the first material and S_1' the yield strength of the second, it is possible to define yield strength in such a way that $\beta = S_1'/S_1$. It will be explained later how yield strength must be defined in order that β will have this value.

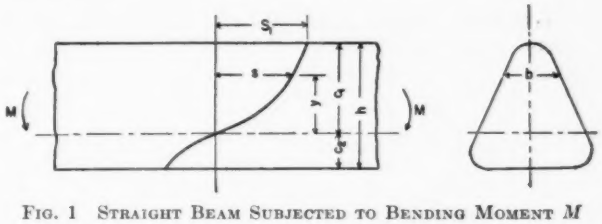

FIG. 1 STRAIGHT BEAM SUBJECTED TO BENDING MOMENT M

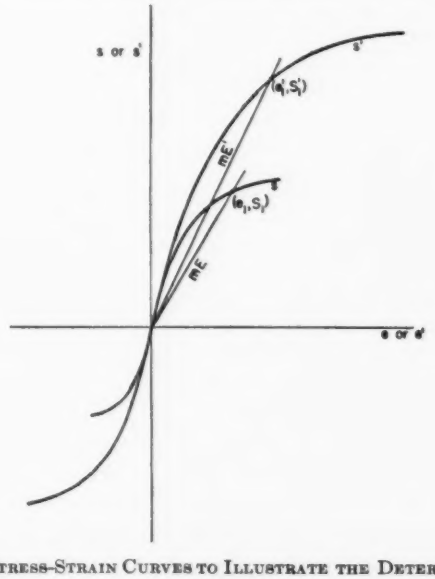

FIG. 2 STRESS-STRAIN CURVES TO ILLUSTRATE THE DETERMINATION OF α AND β

[1] National Bureau of Standards.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until July 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

The determination of α and β is illustrated by Fig. 2, which shows two stress-strain curves, related by Equations [1]. We have for any corresponding points

$$\frac{s'}{e'} = \frac{\beta}{\alpha} \times \frac{s}{e} \quad \ldots\ldots\ldots\ldots\ldots\ldots [3]$$

This equation states that β/α is in the ratio of the secant moduli for corresponding points, which in itself is not of much help. At the origin, however, this ratio is E'/E, the ratio of the moduli of elasticity, a known quantity. Since Equation [3] is an identity, in that it holds for all corresponding points, we see now how to identify such points. The secant moduli for corresponding points on the stress-strain curves must be in the ratio of the moduli of elasticity. Corresponding points, therefore, are the points of intersection with the stress-strain curves of lines through the origin (secant-modulus lines) having slopes proportional to the moduli of elasticity, such as the lines in Fig. 2 with the slopes mE and mE', where $0 < m < 1$. The values α and β are now seen immediately to be given by

$$\alpha = \frac{e_1'}{e_1} = \frac{S_1'/(mE')}{S_1/(mE)} = \frac{S_1'E}{S_1E'} \qquad \beta = \frac{S_1'}{S_1} \ldots\ldots\ldots [4]$$

where the points (e_1, S_1) and (e_1', S_1') are the points of intersection mentioned. The values α and β do not depend upon m because any value of m between 0 and 1 determines corresponding points, and by the hypothesis of Equations [1] α and β are constants. If the stress-strain curves are single straight lines, α and β may have any values subject to the condition $\beta/\alpha = E'/E$.

It now becomes evident how yield strengths must be determined if Equation [2] is to hold. By referring to Equation [4] for β, it is clear that the yield strength must be defined as the stress represented by the intersection with the stress-strain curve of a line through the origin, having a slope m times the modulus of elasticity of the material, where $0 < m < 1$.

Examination of a considerable number of (compressive) stress-strain curves of different materials has shown that, for a given material (as supplied commercially, for example), the relations in Equations [1] do often in fact actually hold to a good degree of approximation. In order to determine whether two stress-strain curves are affinely related, as indicated in Equations [1], it is only necessary to draw several secants with slopes m_1E, m_2E, ... m_nE for the one curve and with slopes m_1E', m_2E', ... m_nE' for the other curve. If the two curves are affinely related, it will be found that the ratios of corresponding strains e_1'/e_1, e_2'/e_2, ... e_n'/e_n are all equal, equal to α, let us say; and that ratios of corresponding stresses s_1'/s_1, s_2'/s_2, ... s_n'/s_n are all equal, let us say equal to β.

The choice of m for determining yield strength is largely a practical matter. If m is taken less than $^1/_2$, the stress-strain curve of the material will have to be obtained for greater strains than is now customary. On the other hand, if m is taken near to 1, the yield strength so determined will be a stress below which little plastic action has occurred.

This method of determining yield strength (in compression) has been used by the author for some years to compensate for variations in test results[2] due to variations in the mechanical properties of the materials of the test specimens. It was being used by the Heintz Manufacturing Company, Philadelphia, Pa., in 1936, according to information received by the author at the time from F. M. Lambert of that company.

Experimental and Theoretical Investigation of a Turbine Foundation

By SERGIUS VESSELOWSKY,[1] DETROIT, MICH.

This paper contains the results of a study made on a turbine foundation for the purpose of elucidating conditions which favor the building up of excessive vibrations when the unit is in operation. The structure studied was a steel framework supporting a concrete table with a turbogenerator erected on it. The experimental part consists of (*a*) dynamical loading of the structure and (*b*) determination of its elastic constants. The theoretical treatment of the problem consists of the determination of the frequencies and the modes of the natural vibrations by analytical methods. A comparison of the theoretical results obtained with the experimental findings is made. The results of the study indicate that vibrations of a turbogenerator on its foundation, for units of conventional design, can be treated as vibratory motion of a deformable body supported by a system of massless springs. Some rules to be followed in designing and means of changing a critical frequency in a desired sense also are included.

The present investigation was undertaken in an effort to eliminate the uncertainty which exists in the design of the foundations for turbogenerators, particularly where a steel substructure is used.

THE first part of the paper consists of a description of tests which were conducted on a foundation supporting a 30,000-kw turbogenerator of conventional design operating at 1800 rpm. The aim of the experimental investigation was (*a*) to locate various critical frequencies at which natural vibrations occur in this type of structure and to find their corresponding modes and (*b*) to determine some of the elastic constants of the structure. This is followed by an analytical treatment of the same problem.

The foundation used for the tests was formed of four steel portals, erected on the principal mat of the Conners Creek powerhouse of The Detroit Edison Company and a heavy concrete table on which the machine was assembled. The mat of the building is a strong plate of reinforced concrete over 6 ft thick and resting on wooden piling of some 25 ft depth. This construction insured a complete immobility of the base of the steel portals supporting the machine. Not even the slightest vibrations were noticeable at these points. The soil under the powerhouse is Detroit blue clay and has permitted a total settlement of the mat from 1924 to 1935 of 2 in.

Figs. 1, 2, and 3 reproduce the structure. Its principal dimensions are: Total length, 47 ft; height of the table over the condenser floor, about 28 ft; width of the concrete table, 28 ft.

The table is a heavy plate of concrete reinforced by a network of steel beams and is mechanically isolated from the rest of the building. On this table is assembled the turbogenerator. The connection between the table and the machine was exceedingly strong. Rigidity of this connection was a very important feature determining the possible deformations of the unit and therefore the modes of the natural vibrations of the system.

Experimental Studies

Natural vibrations of the structure were studied first experimentally by means of a dynamic load. This brought to light critical frequencies of several natural vibrations of the system and revealed their modes, i.e., the configurations through which the system was moving when vibrating. Dynamic loads consisting of harmonic impulses of known direction and frequency were applied at various points while observing the vibrations produced at every frequency in different parts of the structure. These impulses were produced by four vibrators. Each vibrator consisted of a strong frame, supporting between two ball bearings a shaft on which a radial arm was fixed. This arm had two symmetrical openings—one from each extremity. When an unbalance was artificially created, in the form of a bolt inserted into one of the holes of the arm, a rotational radial force due to centrifugal action came into play.

Placing two vibrators, one against the other and letting them run in opposite directions, it was possible to produce only horizontal or only vertical impulses of double intensity.

Each vibrator was rotated by a separate synchronous motor of 7½ hp through a chain drive, which gave an electrically "rigid connection" between different vibrators. All of the motors which operated the vibrators were fed from a common motor generator set, the speed of which could be varied. Thus, it was possible to change the frequency of all the impulses given by the vibrators to the structure without altering their phase relations.

Placing vibrators at different points on the slab and changing the phase difference between individual motors and their vibrators, it was possible to have any desired phase sequence of different impulses in such manner as to give to the slab any desired dynamical loading. Vibrators were bolted very solidly to the table and embedded in about 4 in. of concrete to prevent any local vibrations.

To check the phase sequence of various vibrators already rotating, a stroboscope was used, as well as a special arrangement consisting of sets of contacts attached to the rotating arms of the vibrators so that the correct phase relation of vibrators was made visible at low speed by special signal lights.

The rate of energy consumed by the motor driving the vibrator was measured by wattmeters and their readings plotted against the speed. Noticeable peaks corresponding to critical frequencies were not found on this curve as had been expected.[2] Evidently the greatest part of the energy dissipation was due to

---

Presented at the Fourth National Meeting of the Applied Mechanics Division of The American Society of Mechanical Engineers, Pittsburgh, Pa., June 11–13, 1936. This paper is part of a dissertation submitted in partial fulfillment of the requirements for the degree of doctor of science at the University of Michigan.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until July 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[2] "Technische Schwingunslehre," by W. Hort, J. Springer, Berlin, Germany, 1922, pp. 193–194.

(*a*) to the "softness" of the structure as compared with the strength of the shaft and (*b*) to the fact that the rotating masses form less than one tenth of the whole vibrating system. This can be checked on the known formulas for the critical frequencies of the turbine on an elastic base.[3]

Elastic reactions of the structure, generated by various deformations, were determined either experimentally or analytically. Reactions of the steel framework caused by horizontal deflections were determined experimentally. For this purpose turnbuckles were attached to the columns of the building on one side and to the foundation on the other, at points *A*, *B*, and *C* shown in Fig. 5, with accurate dynamometers inserted between. By tightening the turnbuckles, it was possible to produce any desired intensity of the force measured by the dynamometers. Deflections were measured by two microscopes rigidly fixed to the table at the

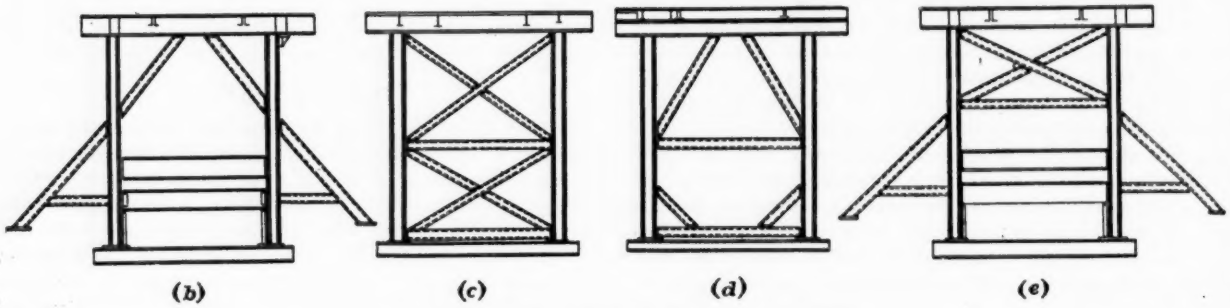

FIG. 1 THE STEEL FRAMEWORK OF THE FOUNDATION

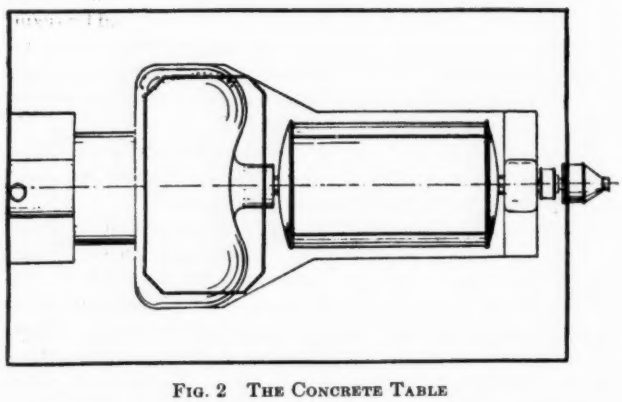

FIG. 2 THE CONCRETE TABLE

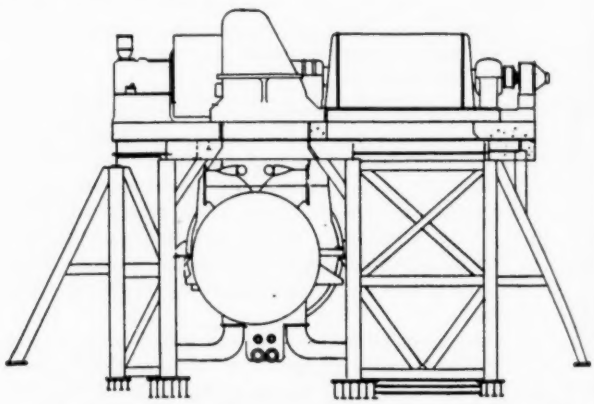

FIG. 3 THE TURBOGENERATOR AND FOUNDATION ASSEMBLY

air resistance of the rotating arms but not due to friction in the structure. The amplitudes of vibrations were measured by a recording Geiger vibrograph.

For every combination of impulses the observed amplitudes were plotted versus the frequency with the setup as described previously. A number of sharp peaks were observed on the curves representing the amplitudes of vibrations (horizontal or vertical) at various points on the slab plotted against the variable frequency of the impulses given to the structure, evidently corresponding to critical frequencies of some modes of vibrations, as shown in Fig. 4.

The results obtained coincided very closely with those obtained by other experimenters in their tests made in other powerhouses of The Detroit Edison Company on various units identical with or similar to that experimented upon by the author. The difference in the experimental setup was that their tests were made, not with the vibrators, but using the unavoidable unbalance of the rotating part, which causes impulses in the bearings of the unit. Evidently the gyroscopic effect of the rotating masses on the whole vibrating system is negligible. This is due

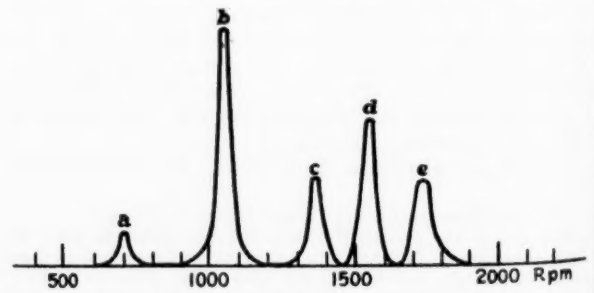

FIG. 4 COMPOSITE FREQUENCY-AMPLITUDE CHARACTERISTIC OF THE UNIT AS OBSERVED

[(*a*) Weak vertical vibrations at the middle of the unit. (*b*) Violent vertical vibrations of the exciter end. (*c*) Vertical vibrations over the entire length of the table with amplitudes increasing away from the axis of the unit. (*d*) Horizontal vibrations especially pronounced in the generator part. (*e*) Vertical vibrations especially pronounced in the turbine part.]

[3] "Steam and Gas Turbines," by A. Stodola, McGraw-Hill Book Co., Inc., New York, N. Y., 1927, pp. 1135–1136.

points D and E, and focused on two immovable scales rigidly attached to special light columns erected on the condenser floor and free from any deflections of the slab. Magnification of the microscopes was sufficient to measure displacements with an accuracy of not less than 0.002 mm. Knowing the displacements of the points D and E, it was possible for every load to determine the deflection of the center of gravity of the total mass and, in the case of the transversal loading, rotation of the longitudinal axis, because the table was not deformed under the action of the applied forces.

Forces in the longitudinal direction were varied from 0 to 20,000 lb, while those in the transverse direction were changed from +10,000 to —10,000 lb.

In most cases when the turbine is directly coupled to the

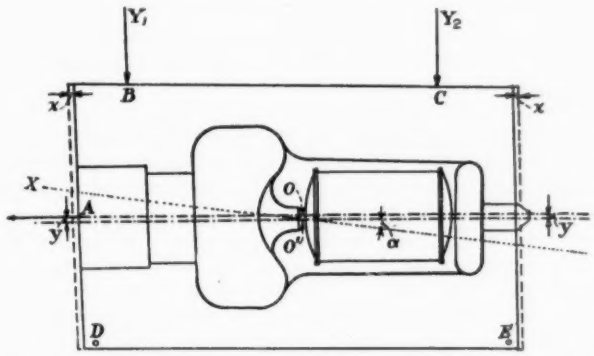

FIG. 5 SETUP OF THE STATIC EXPERIMENTS ON THE UNIT—THE MODE OF LATERAL VIBRATIONS WITH THE TABLE RIGID IS INDICATED

generator, a symmetry exists in the foundation and in the mass distribution of the whole unit with respect to the vertical plane passing through the shaft of the machine. Only the piping could give some asymmetric reactions, but in the present case the asymmetric members were of negligible rigidity. Another feature of the structure studied was the fact that the longitudinal and the vertical deflections of the table were independent of one another. Therefore, the elastic reaction X of the structure in the axial direction could be represented as proportional to the corresponding displacement x. From experiments it was found that

$$X = 5.74 \times 10x \quad \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

wherein X is expressed in pounds per inch.

In the case of a horizontal force Y, applied at the centroid O in the transverse direction, not only would this point be deflected y inches from its position of equilibrium, but simultaneously the whole table would be rotated through an angle α, because the resulting reaction of the structure would not, in the general case, pass through the point O; inversely to any pair of values y and α would correspond a transverse force applied at O and a moment M acting around the vertical axis through O.

The statical tests made it possible to establish relations between these quantities. For the foundation investigated these relations could be represented by two linear equations

$$Y = (3 \times 10^6 y) + (170 \times 10^6 \alpha) \ldots\ldots\ldots\ldots [2]$$

$$M = (170 \times 10^6 y) + (178 \times 10^9 \alpha) \ldots\ldots\ldots\ldots [3]$$

where y is measured in inches and α in radians. Therefore, the potential energy stored in the structure, after a deflection determined by coordinates y and α, was

$$V_s = \left(3 \times 10^6 \frac{y^2}{2}\right) + (170 \times 10^6 y\alpha) + \left(178 \times 10^9 \frac{\alpha^2}{2}\right) \ldots [4]$$

ANALYTICAL DETERMINATION OF THE VERTICAL RIGIDITY OF VARIOUS PARTS OF THE STRUCTURE

The important features of the structure on which the computations were based are the following: (1) The bottom of the steel structure remained immovable, being fixed to the principal mat of the powerhouse. (2) The foundation and the unit were symmetrical with respect to the vertical plane passing through the shaft. (3) The concrete table was assumed rigid if acted upon by forces contained in its plane, therefore, the top ends of the columns could be deflected only as a movement of the whole unit. (4) The forces acting on the structure during the vibrations were symmetrical harmonic impulses of high frequency. (5) The knots of the steel structure are assumed to be perfect joints.

It follows from (2) that under the action of vertical forces symmetrically distributed over the table, no transverse deflection of the unit will take place. Further, it can be concluded from (4) that an axial deflection of the table, acted upon by vertical impulses, will also be impossible because the natural frequency of the longitudinal vibrations of the unit (435 cycles per min) is much lower than that of the impulses taken place during vertical vibrations (1050 or 1735 cycles per min). The top ends of the columns, therefore, undergo deflections only in the vertical direction; they are vertically guided. In this case a distinction is to be made between a "statical" loading of a structure and a "dynamic" one, in which inertia forces may become very important.

Based upon these premises and using familiar methods of the theory of frames, the spring constants of four portals shown in Fig. 1 were computed, assuming every portal independent of the rest of the structure. With the modulus of elasticity of steel equal to 30×10^6 lb per sq in., these constants were found: $K_1 = 11.5 \times 10^6$; $K_2 = K_3 = 8.5 \times 10^6$ lb per in.; and $K_4 = 10.5 \times 10^6$ lb per in.

Masses of different parts of the unit and their moments of inertia with respect to various axes and planes were determined partly by direct weighing of these members and partly by geometric measurements and computations. This was possible on disassembling the unit and demolishing the whole structure when, for example, the density of the concrete of the table was determined by weighing blocks of concrete in air and in water. Centroids of some of the parts were determined by weighing them, using various points of attachment. The greater part of the combined masses and of the total moments of inertia came from the widespread concrete table of the unit. Its simple geometric form made the computations quite accurate. The fact that most of the parts of machinery are bodies of revolution facilitated the computations.

The vibrating system under study was composed of the turbogenerator, rigidly connected with the table, the condenser, and the steel substructure. The weight of the machine and of the table was about 1,100,000 lb; the condenser which participated in the vertical vibrations had a weight of over 250,000 lb. On the other hand, the weight of the substructure was only about 50,000 lb, of which only 17,000 lb were to be added to the vibrating masses. It is evident that the vibratory motion of the unit can be considered as that of a body, rigid or deformable as it may be, on a system of massless springs. Other important features of the structure were the independence of the vertical and the horizontal vibrations from one another and the symmetry of the structure and of the mass distribution with reference to the vertical plane passing through the shaft of the machine.

It follows from this that if the table were rigid the vibratory motion of the unit would have, in the general case, six degrees of freedom, but in the case under consideration this motion can be split into four independent modes of vibrations with no more than two degrees of freedom each. These modes are (1) longitudinal vibrations with just one degree of freedom when the unit vibrates back and forth in the axial direction with purely translatory motion; (2) rolling vibrations also with one degree

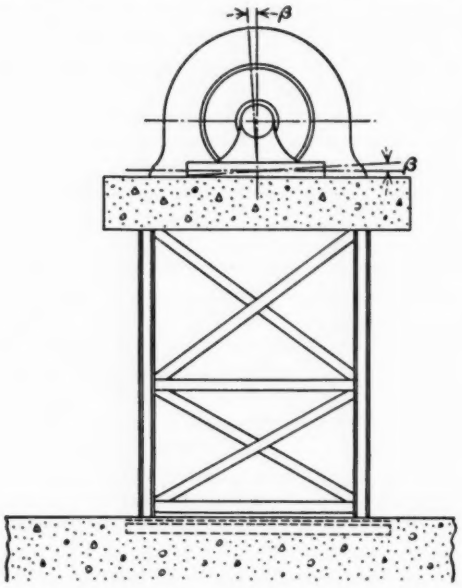

FIG. 6 ROLLING VIBRATIONS OF THE UNIT

of freedom around the horizontal axis passing through the common centroid parallel to the shaft as shown in Fig. 6; (3) horizontal transverse vibrations with two degrees of freedom, given by the variation of the linear transverse deflection y of the common centroid of the unit and the rotation α of the table about the vertical axis passing through the centroid (yawing) as shown in Fig. 5; (4) the vertical vibrations also with two degrees of freedom, determined by the vertical deflections of the centroid in the plane of symmetry and the rotation φ of the table about the horizontal axis passing through the centroid and perpendicular to the shaft (pitching).

The analytical determination of the frequencies corresponding to the modes of vibrations described was done according to the methods established in the theory of vibrations.[4] For the unit under study the frequency of the longitudinal vibrations was determined to be 435 cycles per min, while transverse vibrations were found to have frequencies of 297 and 435 cycles per min. The highest frequency found was that of the "rolling" vibrations. The computations gave a value of 1295 cycles per min; observations during dynamic tests have given the value of 1375 cycles per min.

Experimental verification of these results by a dynamical loading of the structure was not possible, except for the rolling of the unit, because the remaining frequencies for the case of a rigid unit were too low and the impulses of the vibrators were too weak at these speeds. But the observations on three different sizes of turbogenerators of The Detroit Edison Company during the periods of putting them on the line revealed these frequencies and confirmed that in accordance with the analytical findings they are very low for the units of the conventional design, that is, with the machine assembled on a high substructure and with the condenser and the air cooler beneath.

Vertical vibrations of the unit observed during the tests were accompanied by very obvious deformations of the table. Therefore, no computations are given here for the case of a rigid table vibrating vertically. The treatment of a more general case, i.e., of the vertical vibrations of the unit with the table bending in its middle part is discussed later.

CASE OF DEFORMABLE TABLE

Vibration of a turbogenerator with its table rigid, assembled on a system of massless springs, would be a vibratory motion with six degrees of freedom. The dynamic tests showed that the table did not remain rigid either in the horizontal or in the vertical direction. The vibratory motion of a deformable unit of the type studied can be described with sufficient accuracy as having eight degrees of freedom, one additional coordinate each being necessary to describe the configuration of the deformed unit in both horizontal or vertical vibrations.

The fact that the table underwent a noticeable deformation during both vertical and horizontal vibrations does not influence the separation of the general vibratory motion into four mutually independent modes due to symmetry of the structure as described. Thus, the longitudinal vibrations occurred as previously and with no deformation of the table in this mode. The same is to be said about the rolling of the unit. It is important to note that the modes of natural vibrations which can have frequencies approaching the operating speed of the unit (1800 or 3600 rpm) will be only those combined with the deformations of the unit. This makes it imperative to analyze what deformations of the unit are probable.

A characteristic feature of the design of the turbines, used by The Detroit Edison Company, is the great rigidity of the turbine shell and its strong connection with the table. In the case studied by the author the lower half of the turbine shell, weighing over 50,000 lb, was deeply imbedded in the concrete of the table and bolted solidly to its reinforcing beams. Therefore the turbine part of the unit remained rigid during both the vertical and the horizontal vibrations, in spite of the great opening in the table for the exhaust steam. The remaining parts of the system underwent deformations and these were different in the case of the horizontal or the vertical vibrations.

What can be the deformation of the system in the first case under the action of a horizontal force applied at the exciter bearing, as an unbalanced rotor would act? It can be easily seen that only the bedplate of the generator adds to the strength of the table, being immersed in its concrete. The generator itself does not add much to the strength of the corresponding part of the table because the stator, in spite of its impressive weight (130,000 lb), has a very low flexural rigidity against forces acting perpendicular to its axis, being constructed of some 50 bundles of stampings of laminated iron sheets, with as many air ducts in between, and held together by a very light frame. This explains why the table acted upon by a horizontal force applied at the exciter end was not only rotated on the steel substructure but was also deformed in its plane all over the generator length. By the reasons explained later the condenser did not participate in these deformations.

Therefore, our system vibrating horizontally consisted of the machine and the table, and assumed the shape represented in Fig. 7*b*.

The deformations observed during the vertical vibrations of the unit were quite different. As can be seen from Fig. 8*a*, the vibrating system, consisting of the turbine with its condenser, the generator, and the table, is particularly characterized by a great reduction of its flexural rigidity in the indentation between

[4] "Vibration Problems in Engineering," by S. Timoshenko, D. Van Nostrand Co., Inc., New York, N. Y., second edition, 1937, art. 40.

the turbine shell and the generator. This was due (1) to the very configuration of the turbogenerator representing two different machines coupled together; (2) to the presence of a bolted joint between the lower exhaust shell of the turbine and the bedplate of the generator; and (3) to the discontinuity of the longitudinal steel beams *B10-B13*, which are cut twice by the transverse beams *B21* and *B7*, as shown in Fig. 1*a*. The rigidity of the unit in this indentation, compared with that in other vertical cross sections, was so small that it can be considered as a very flexible joint.

Another cross section, having a very low rigidity was the hood connecting the exhaust shell of the turbine with the condenser. The great inertia reaction of the massive condenser (250,000 lb weight) at the frequencies observed (1050 and 1735 cycles per min) caused a bending of the hood, which is built as a frustum of a pyramid 60 in. in height with very thin walls (1 in.) bolted to the turbine shell and to the condenser. It can be proved easily that the hood was too flexible to transmit horizontal components of the vibrations of the condenser body. Therefore the condenser was not vibrating during horizontal vibrations of the unit. On the contrary, the vertical component of the inertia reaction cannot cause a noticeable deformation of the hood and, as a result, the centroid of the condenser followed the vertical movements of the point B of the turbine shell as shown in Fig. 8*b*.

Finally it can be assumed with a great degree of approximation that the deformations of the unit were plane deformations, since the cross beams of the table were not deformed. The horizontal transverse and the vertical vibrations of a unit with the deformable table are treated in the following manner.

Horizontal Vibrations (Transversal)

On placing the vibrator near the exciter bearing and letting it run so that horizontal impulses perpendicular to the shaft direction were given to the slab, a mode of vibration was found with a critical frequency of nearly 1550 cycles per min having highest amplitudes at the middle part. The observed vibrations were horizontal and were combined with an evident deformation of the table, as represented in Fig. 7*a*.

Transverse vibrations of a rigid table, as explained, occur as motion with two degrees of freedom. The deformation of the table increased the degrees of freedom of the unit by the number of coordinates which were necessary to determine this deformation. Using the approximation suggested in the treatment of similar problems by Lord Rayleigh,[5] the elastic line of the deformed vibrating generator part was assumed to be identical with the elastic line caused by the action of a horizontal transverse force applied to the exterior bearing. An unbalanced rotor would act in this way. Then the deformation of the whole generator part could be determined by just one coordinate, i.e., by the linear deflection d of the end point D from its position on the rigid table. The deflection of any intermediate point (from its position on the rigid table) would be equal to kd, where k is a dimensionless factor fully determined by the (assumed) shape of the elastic line. Therefore, in the case of a deformable table, the transverse vibratory motion of the unit is determined kinematically by the three coordinates, y, α, and d, transverse deflection of the centroid, rotation of the table, and its deformation at the exciter end, respectively.

Placing the zero of the coordinates axes in the centroid O of the system so that the X-axis coincides with the shaft of the machine and the Y-axis is directed as shown in Fig. 7*b* the following relations can be established between the coordinates ξ_i,η_i of the point P at any instant and its coordinates ξ,η in the equilibrium position

$$\xi_i = \xi - \eta\alpha; \quad \eta_i = y + \eta + \xi\alpha + kd$$

By differentiating with respect to time, and squaring and adding, the velocity v of the point P can be expressed as

$$v^2 = \dot{y}^2 + r^2\dot{\alpha}^2 + k^2\dot{d}^2 + 2\xi\dot{y}\dot{\alpha} + 2k\dot{y}\dot{d} + 2\xi k\dot{\alpha}\dot{d} \quad \ldots\ldots [5]$$

where r is the distance of the point P from the centroid; the three coordinates y, α, and d have the same values for all points of the unit; and ξ and k are constant for a transverse strip of the table.

Dividing the generator part into ten transverse strips and knowing the mass m contained in each of them, it is possible to compute the kinetic energy of the vibrating unit

$$T = \frac{1}{2}\Sigma mv^2 = \frac{1}{2}My^2 + \frac{1}{2}I\dot{\alpha}^2 + \frac{\dot{d}^2}{2}\Sigma mk^2 + \dot{y}\dot{d}\Sigma mk + \dot{\alpha}\dot{d}\Sigma mk\xi \quad \ldots\ldots [6]$$

The first two terms in the expression for T are identical with those obtained for a rigid table; the last three, containing the

[5] "Theory of Sound," by Lord Rayleigh, vol. 1, Macmillan and Company, London, 1896.

FIGS. 8a AND 8b THE UNIT AND ITS DEFORMATIONS DURING VERTICAL VIBRATIONS
FIG. 8c MODES OF THE VERTICAL VIBRATIONS

factor k, are the result of the deformation of the generator part. For the rigid turbine part they are equal to zero for all points. The term $\Sigma m\xi$ is equal to zero with the ordinate axis passing through the centroid of the system.

The rigid turbine part of the unit extended up to the cross section PQ, determined by the configuration of the lower very strong shell of the turbine shown in Fig. 7a. The expressions Σmk^2, Σmk, and $\Sigma mk\xi$ for the unit studied were computed to be, respectively, equal to 840, 1000, and 175,000; the dimensions of the first two figures are lb-mass; of the last lb-mass multiplied by inch. The total mass M of the vibrating system was 2760 lb-mass and the moment of inertia I with respect to the vertical axis through the centroid was computed to be 91×10^6 lb-mass $\times$ in.^{2} Thus the kinetic energy T of the vibrating system was equal to

$$T = 2760\frac{\dot{y}^2}{2} + \left(91 \times 10^6 \frac{\dot{\alpha}^2}{2}\right) + 840\frac{\dot{d}^2}{2} + 1000\,\dot{y}\dot{d} + 175{,}000\,\dot{\alpha}\dot{d} \ldots [7]$$

The potential energy of the deformed structure consisted of two parts: (1) The energy V_s stored in the steel structure, as determined by the static tests and corrected for the additional deflection of the fourth portal due to deformation d of the table; and (2) the energy V_c stored in the deformed concrete table. The potential energy stored in the steel substructure after the table had undergone a deflection determined by the coordinates y and α was determined from static tests.

Deformation of the generator part affected only the portal supporting the exciter bearing. The spring constant of this portal in the transverse direction was computed equal to 0.8×10^6 lb per in. It is evident that the deflection (y, α) caused a reaction in the fourth portal equal to $0.8 \times 10^6\,(y + l\alpha)$, where l is the distance of this portal from the centroid (187 in. in this case). A deflection d increases this reaction to the value $0.8 \times 10^6\,(y + l\alpha + d)$. Therefore, the potential energy stored in the portal due to the deflection d was equal to $0.8 \times 10^6\,[y + l\alpha + (d/2)]d$.

The energy V_c stored in the deformed concrete table was determined analytically by computing the deformation of the plane frame as represented by Fig. 7a. To the left of the cross section PQ the table was rigid, at the point D it was acted upon by a horizontal, transverse force. The angle connections were assumed rigid and areas and moments of inertia of various members were computed from the drawings, assuming the ratio of the moduli of elasticity for steel and concrete equal to ten (average for tension and compression). The numerical value of V_c for this table was $1/2 \times 1.1 \times E_c d^2$, where E_c is the modulus of elasticity for the concrete and d is the deflection of the point A; E_c can vary[6] from 2.25×10^6 up to 3.50×10^6 lb per sq in. Thus V_c can be written as $1.1 \times B \times 10^6(d^2/2)$, where B is a numerical factor varying from 2.25 to 3.50.

Therefore, the potential energy V of the system in the position determined by the coordinates y, α, d is

$$V = \left(3 \times 10^6 \frac{y^2}{2}\right) + (170 \times 10^6 y\alpha) + \left(178 \times 10\,\frac{\alpha^2}{2}\right) + \left[0.8 \times 10^6\left(y + 187\alpha + \frac{d}{2}\right)d\right] + \left(1.1 \times 10^6 B\,\frac{d^2}{2}\right) \ldots [8]$$

Forming Lagrange's equations of the vibratory motion, we obtain the system

$$\left.\begin{aligned} &2760\ddot{y} + 1000\ddot{d} + (3 \times 10^6 y) + (170 \times 10^6\alpha) + (0.8 \times 10^6 d) = 0 \\ &(91 \times 10^6\ddot{\alpha}) + 175{,}000\ddot{d} + (170 \times 10^6 y) + (178 \times 10^2\alpha) + (150 \times 10^6 d) = 0 \\ &1000\ddot{y} + 175{,}000\ddot{\alpha} + 840\ddot{d} + (0.8 \times 10^6 y) + (150 \times 10^6\alpha) + 10^6(1.1B + 0.8)d = 0 \end{aligned}\right\} \ldots [9]$$

Proceeding in the usual way[7] and assuming for E_c the value 2.75×10^6, the frequency equation was obtained in the form

$$p^6 - 31{,}081p^4 + (81 \times 344 \times 536p^2) - (50 \times 533 \times 647 \times 960) = 0 \ldots [10]$$

[6] Data about the values of E_c can be found in "Die Druckelastizität und Zugelastizität des Betons," by Otto Graff, *Forschungsarbeiten auf dem Gebiete des Ingenieurwesens*, No. 227, 1920. Also "Modulus of Elasticity of Concrete," by S. Walker, Bulletin No. 5, Lewis Institute, Chicago, Ill.

[7] Loc. cit., footnote 4, art. 37.

giving for the circular frequency p the values 168; 43 and 31, or 1605; 411 and 297 cycles per min.

The dynamic tests have established only the highest of the computed critical frequencies, i.e., the highest one at 1550 cycles per min. The two others were too low to be noticeable under the impulses of the vibrators used. However, natural vibrations (transverse horizontal) of such low frequencies were observed on several units in the powerhouses of The Detroit Edison Company.

Substituting every one of the values of p^2 in the system of Equations [9], the constant ratios of amplitudes Y, A, D (corresponding to coordinates y, α, d) were found for every p^2. This made possible the establishment of the mode of the vibrations corresponding to this frequency. For $N_1 = 1605$ and for an arbitrary value of Y, the values of A and D are given by the equations

$$A = Y/183 \quad \ldots\ldots [11]$$

$$D = 2.7Y \quad \ldots\ldots [12]$$

The shape of the deformed table as determined by these relations is represented by Fig. 7*c*. Analogously, for $N_2 = 411$, $A = Y/35.5$ and $D = 2.6Y$. Finally, for $N_3 = 297$, indicated in Fig. 7*c*, $A = -y/531$ and $D = 0.04Y$.

As can be seen from Fig. 7*c* for $N_1 = 1605$, the greatest amplitudes were to be expected in the middle of the table. The ends of the table were almost immovable, because at the turbine end rotations almost annihilated the transversal vibrations and at the exciter end the deflections due to flexibility of the table were equal and opposite to the combined deflections caused by the translation and rotation. This explained very well the observations made during dynamic tests (compare part *d* of Fig. 4).

It is interesting to note that the modes of the slower vibrations of 411 and 297 cycles per min were very similar to those of a rigid table.

Vertical Vibrations of the System

The dynamic tests showed that at about 1735 cycles per min the maximum of the amplitudes was observed near the exterior bearing of the turbine with much smaller ones at the exciter. At about 1050 cycles per min, the greatest amplitudes of vibrations took place at the points near the exciter end of the generator, the turbine part up to the middle of the unit remaining almost immovable. Finally, at about 700 cycles per min, the maximum of the amplitudes was observed in the middle of the unit. The last vibrations were very weak due to the insufficiency of the impulses given by the vibrators at this speed. In any case, there was no doubt that a bending of the structure occurred during both vibrations somewhere near the middle of the unit.

The instantaneous position of the vibrating system is fully determined by three coordinates; the linear deflection z of the slab at the point A, shown in Fig. 8*b*, and the two angles φ and ψ formed by each half of the table with the horizontal, shown in Fig. 8*b*. The positions of the three bodies forming the vibrating system, i.e., of the turbine part, of the generator part, and of the condenser part, are readily expressed as functions of these coordinates. Knowing all masses, their centroids, and the moments of inertia, the kinetic energy of the system can be determined in terms of the coordinates chosen.

The elastic elements of the system were formed by the four supporting portals. The potential energy was determined from their computed spring constants and their deflections. The table was assumed perfectly flexible in its middle part.

Referring to the configuration of the deformed system shown in Fig. 8*b* with the dimensions indicated, the potential energy V and the kinetic energy T of the vibrating system can be written as

$$V = {}^1/_2\, k_1 z^2 + k_2(z + 67.5\varphi)^2 + k_3(z + 260\varphi + 30\psi)^2 + k_4(z + 260\varphi + 210\psi)^2 \ldots [13]$$

$$T = {}^1/_2 M_t(\dot{z} + 130\dot{\varphi})^2 + {}^1/_2 I_t\dot{\varphi}^2 + {}^1/_2 M_g(\dot{z} + 260\dot{\varphi} + 129\dot{\psi})^2 + {}^1/_2 I_g\dot{\psi}^2 + {}^1/_2 M_c(\dot{z} + 170\dot{\varphi})^2 \ldots [14]$$

Here M_t denotes the mass of the turbine and the supporting part of the table equal, as computed, to 1260 lb mass; M_g is the mass of the generator with the corresponding part of the table equal to 1512 lb mass; M_c is the mass of the condenser equal to 650 lb mass; I_t denotes the moment of inertia of the mass M_t with respect to the horizontal transverse axis passing through the centroid of M_t, and was computed equal to 12×10^6 lb $\times$ in.^{2}; I_g is the moment of inertia of the mass M_g with respect to the horizontal transverse axis passing through its centroid, and was computed equal to 14×10^6 lb $\times$ in.^{2} With these values of the coefficients, the expressions for V and T become

$$V = \frac{10^6}{2}(39z^2 + 1{,}323{,}000\varphi^2 + 471{,}000\psi^2 + 2z\varphi\ 5500 + 2z\psi\ 2460 + 2\varphi\psi\ 640{,}000) \ldots [13a]$$

$$T = {}^1/_2[3420\dot{z}^2 + 154.3 \times 10^6\dot{\varphi}^2 + 39 \times 10^6\dot{\psi}^2 + 2\dot{z}\dot{\varphi}\ 667{,}000 + 2\dot{z}\dot{\psi}\ 195{,}000 + 2\dot{\varphi}\dot{\psi}\ 51 \times 10^6] \ldots [14a]$$

Knowing V and T, Lagrange's equations for the vibratory motion of the system are readily derived, and for harmonic variations of the coordinates with a circular frequency p, the following system is obtained:

$$\left.\begin{aligned}(39 - 0.00342p^2)Z + (5500 - 0.667p^2)\Phi + (2460 - 0.195p^2)\Psi &= 0\\ (5500 - 0.667p^2)Z + (1{,}323{,}000 - 154.3p^2)\Phi + (640{,}000 - 51p^2)\Psi &= 0\\ (2460 - 0.195p^2)Z + (640{,}000 - 51p^2)\Phi + (471{,}000 - 39p^2)\Psi &= 0\end{aligned}\right\} \ldots [15]$$

Thus, the frequency equation becomes

$$p^6 - 48{,}574p^4 + 603{,}044{,}000p^2 - 1{,}956{,}477{,}030{,}000 = 0 \ldots [16]$$

The three roots of this equation are $p_1^2 = 31{,}309$, $p_2^2 = 12{,}100$, and $p_3^2 = 5164$; therefore, the corresponding critical frequencies are 1690, 1050, and 686 rpm. The values observed during the tests were 1735, 1050, and 700 rpm, respectively. Substituting each one of the found values of p^2 into the system of Equations [15], the corresponding mode of natural vibration was determined. Fig. 8*c* represents the configuration of the longitudinal axis of the unit deformed in the three modes determined in this manner.

Comparison of Fig. 8*c* with the results of the dynamic tests represented in Fig. 4 (peaks *a*, *b*, *e*) shows that in the case of the vertical vibrations the agreement between the theoretical findings and the results of the experiments is very good and better than for horizontal vibrations. This is due principally to more accurate knowledge of the elastic constants of the structure.

Conclusions

The experiments and the analytical study just described show that the vibrations of the turbogenerator on its foundation of the type considered can be treated as a vibratory motion of an elastic body supported by a system of massless springs. The classical methods of analytical mechanics give very satisfactory explanation of the phenomena observed during tests of the unit.

If the steel substructure considered in this case were replaced

by a system of concrete portals, vibratory motion of such a unit can be also treated as has been done in the present study. The same method often can be applied to foundations for other types of machines, such as motor generator sets and electrically driven fans.

It is always possible to design a foundation for a steam turbine so that it will be free from resonance with the operating speed (1800 to 3600 rpm) if the table be built rigid. This is so important an advantage that it is worth while relinquishing the conventional type of table and adding to it some elements of trusses in the vertical planes to increase its rigidity.

If the table is deformable, as it usually is, and if the critical frequency falls near the operating speed, two cases are equally possible: (1) Critical frequency is below the operating speed, and (2) critical frequency is higher than the operating speed. Only in the second case will a strengthening of the structure, so often resorted to by a practical engineer, bring favorable results. In the first case such a measure can make the situation worse by bringing the critical frequency of the structure nearer to the operating speed where instead an increase of dead mass would be indicated.

Analysis of the dynamic properties of a given foundation and determination of the causes and remedies of a roughly running unit can be made only if the design of the structure is as simple as possible. Holes, recesses, and brackets must not complicate the initially simple form of a foundation to such an extent that accurate computation of the rigidity of many members is impossible. A complete consolidation must be achieved between such elements of compound members of the structure as the bed plate of the machine, the concrete slab, and its reinforcing beams.

In solving the problem analytically, satisfactory results can be obtained only by treating the vibratory motion in a most complete and rigorous way. Any attempt to simplify the problem and to treat different modes of vibrations observed as independent vibratory motions of various parts of the unit with others immovable, will, generally speaking, lead to erroneous results.

As a rule, the vibrating system must be analyzed as an integral unit. Frequencies of various modes of vibrations of the unit with their antinodes in various planes of the structure are nothing but different roots of the same "frequency equation," derived from the dynamic relations controlling the vibratory motion of the whole unit.

It would be hopeless to expect great accuracy of the numerical values obtained by an analytical treatment of the problem. They are often affected by many incertitudes, e.g., those inherent to computations of the steel trusses, or those caused either by the variations in the value of the modulus of elasticity of concrete or by the errors in the evaluation of the strength of some machine parts.

It is important to note that the computed modes of vibration do not change much with the variation of the numerical values of critical frequencies. Consequently, conclusions may be drawn, on the basis of the established mode of vibrations, about the effectiveness of any change in the structure.

Analysis of factors controlling the vibratory motion of a turbogenerator on its foundation clearly shows that many recommendations of various authorities on turbine foundations are illogical. Resonance, which ought to be carefully avoided, is determined by the elastic properties of the structure and by the masses and their distribution. Adherence to any arbitrary limiting value of static deflection or stress as prescribed by some authorities is by no means a measure of safety or a condition for success. Other authorities[8] prescribe to design the various portals of a foundation structure in such a way that their individual critical frequencies should be identical. This consideration can be completely omitted. These same experts insist on the separation of a turbine foundation from the common foundation mat of a powerhouse. In the opinion of the author, this separation is also unnecessary and can create great difficulties with piping.

The influence of various details of the machinery can be very great. For instance, if the "rigid connection" between the turbine and the condenser were to be replaced by an expansion joint, usual in Europe, the immediate result would be a substantial rise of the vertical frequency (1735 cycles per min in the case analyzed) due to the elimination from the vibrating system of a very important mass.

Acknowledgment

This study has been made possible, thanks to the scientific approach to engineering problems manifested by the late C. F. Hirshfeld, former chief of research, and by J. W. Parker, vice-president of The Detroit Edison Company.

To Professor S. Timoshenko, the author owes deep gratitude for his untiring interest in the present study and his advice in the many difficulties encountered. Many of the author's fellow engineers of The Detroit Edison Company helped in the experimental part of the study. The writer wishes to express his special thanks to A. C. Pasini, technical engineer of the Conners Creek powerhouse, and to his colleagues, Messrs. E. T. Cope and D. E. F. Thomas of the research department for their valuable cooperation during the tests.

Critical-Speed Behavior of Unsymmetrical Shafts

By H. D. TAYLOR,[1] SCHENECTADY, N. Y.

The development of large two-pole turbine generators with rotors running above the critical speed, and having long core bodies slotted for field coils, makes desirable a working familiarity with the vibrational characteristics of unsymmetrical shafts. It is the purpose of this paper to describe these characteristics which are distinctly peculiar. This problem has received some attention from previous writers (6–9),[2] who have pointed out an unstable range of operation due to dissymmetry of the shaft, and some of whom made small-scale tests for demonstration. In the present investigation, experimental work on a special rotor of $10^1/_2$ ft span and weighing over 5000 lb was carried out, to test in some detail the indications of a thorough analysis of the problem by the late V. Petrovsky of the Lynn Works of the General Electric Co. This analysis is given in outline in an Appendix.

The first part of the paper deals briefly with the static characteristics of unsymmetrical shafts, as a basis for defining the "degree of dissymmetry." The critical-speed behavior of ordinary round shafts is then reviewed and the theoretical differences due to dissymmetry are described. These are: (*a*) With moderate dissymmetry compared with the degree of damping, a *marked increase in the critical-speed amplitude*, and a *pronounced variation* in the amplitude *with the angular position of the unbalance* of the rotor; (*b*) with greater dissymmetry, beyond a limiting value, an infinite critical-speed amplitude, or rather, two infinite peaks, with unstable operation between them; (*c*) considerable distortion of the phase-angle curves, such that in general the phase angle may be much larger or smaller than 90 deg at the critical speed; (*d*) *double-frequency vibration*, if the shaft is horizontal, with an auxiliary peak, or "subcritical" at half the main critical speed.

Tests on the 5000-lb rotor are described which give general confirmation of these characteristics.

THE effects of an unsymmetrical cross section on the vibrational or "whirling" characteristics of high-speed rotors, such as long two-pole turbine generators, are remarkable—even startling, to those familiar with ordinary critical-speed phenomena but unacquainted with this special subject. Previous writers (6, 7, 8, 9) have pointed out that a rotor with an unsymmetrical shaft may have two peculiarities: (*a*) Unstable operation over a range of speed lying between the two critical speeds corresponding to the principal axes of inertia, and (*b*) double-frequency vibration, with a resonant peak at about half the ordinary critical speed. This second point has also been dealt with by other writers who have omitted all reference to the first.

The purpose of this paper is to present the peculiar theoretical characteristics of unsymmetrical shafts in relatively simple quantitative terms on the basis of an independent analysis; and to describe their general confirmation by shop tests on a special 5300-lb rotor. This subject is of current interest because of the recent development of large two-pole turbine generators having the critical speed of the rotor well below the running speed of 3600 rpm, and with the possibility of an appreciable degree of dissymmetry due to the slotting of the rotor body for the field coils.

Notation

The nomenclature used in this paper is as follows:

a = damping ratio, $= b/\sqrt{cm}$ $(= E/r_s$ for $u = 1)$
b = damping constant, force per unit of velocity
c = stiffness constant of shaft, average, $(c_1 + c_2)/2$
c_1 = stiffness constant of shaft, minimum, along weak axis
c_2 = stiffness constant of shaft, maximum, along stiff axis
d = dissymmetry ratio, defined in Equation [1]
D = damping force
E = eccentricity of center of gravity
F = resultant deflecting force on shaft
h = $(c_2 - c_1)/2$, so that $c_1 = c - h$ and $c_2 = c + h$
m = mass of rotor $= W/g$
r_g = radius of path of center of gravity
r_s = radius of path of shaft center, or deflection
$\bar{r}_s$ = reflection of r_s, as vector, in OX axis (stationary)
$\bar{r}_s'$ = reflection of r_s, as vector, in OX' axis (rotating)
r_y = radius of static-deflection circle, $(y_1 - y_2)/2$
R = radial component of deflecting force
T = tangential component of deflecting force
u = relative speed, running speed/critical speed
W = weight of rotor = mg
x = horizontal component of static deflection
y = vertical component of static deflection
y_1 = maximum static deflection, weak axis vertical
y_2 = minimum static deflection, stiff axis vertical
y_{ave} = average static deflection, $(y_1 + y_2)/2$
α = angle between deflection and weak axis
β = angle between deflecting force and weak axis
δ = angle between unbalance vector and weak axis
ω = speed, radians per sec
ϕ = phase angle between unbalance vector and deflection

NOTE: Bold-face type indicates vector quantities.

Static Characteristics of an Unsymmetrical Shaft

Some of the static characteristics of an unsymmetrical shaft are interesting and have an important bearing on the running characteristics. Fig. 1 illustrates the variation in the static deflection of a horizontal shaft, if it is rolled over slowly, the deflection being a maximum when the "weak axis" is vertical

Presented at the Annual Meeting, New York, N. Y., December 3–8, 1938, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until July 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

(position A) and a minimum when the weak axis is horizontal (position C). (Here the "weak axis" means the axis *along* which the stiffness is a minimum.) For intermediate positions (as at S) the shaft center traverses a *circular path* through the extreme points, and makes *two complete circuits* of this path per revolution of the shaft.

It is this variation in the position of equilibrium of a horizontal

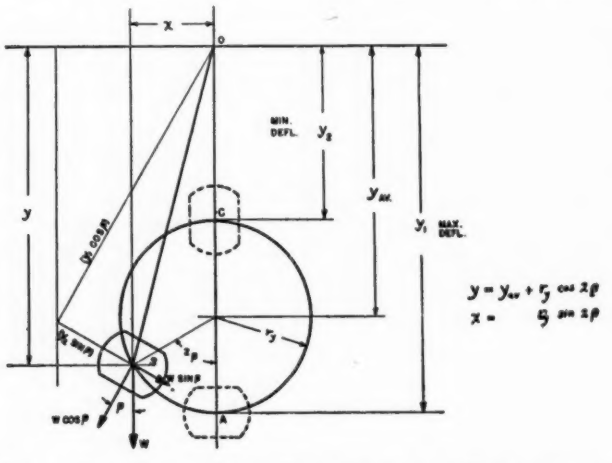

FIG. 1 VARIATION IN STATIC DEFLECTION OF AN UNSYMMETRICAL SHAFT

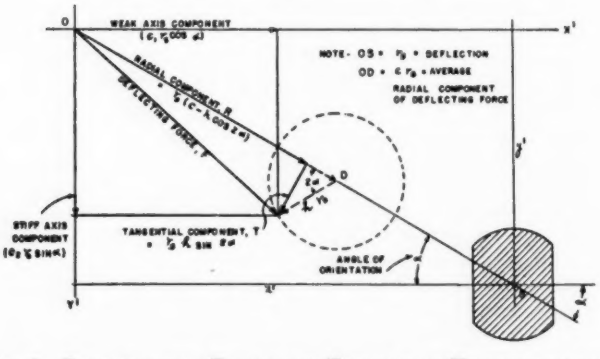

FIG. 2 COMPONENTS OF DEFLECTING FORCE ON AN UNSYMMETRICAL SHAFT, RELATIVE TO DEFLECTION OS

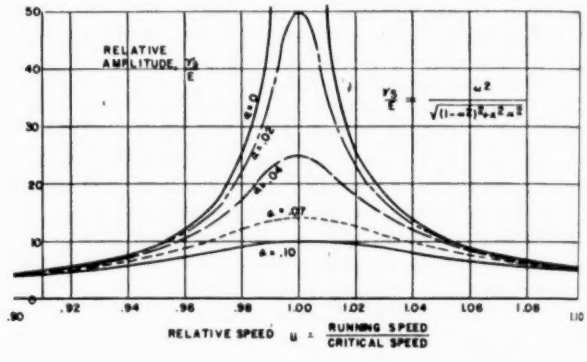
unsymmetrical shaft that is responsible for a disturbance when the shaft is running, substantially like that which would be due to a mechanical unbalance rotating at twice shaft speed, producing double-frequency vibration of the shaft, with a resonant peak at a shaft speed of about half the average fundamental critical speed. An analytical study of this double-frequency shaft vibration is given in the Appendix and test observations on the 5300-lb rotor will be included later.

With regard to the main critical speed, another static characteristic is of perhaps more vital concern, that is, the variation in the force required to impose a constant deflection on an unsymmetrical shaft. This is illustrated in Fig. 2. The force required to produce the deflection OS is obviously a minimum when the weak axis is in line with the deflection ($\alpha = 0$); and a maximum when at right angles ($\alpha = 90$ deg). For an intermediate position, as shown, the deflecting force F may be represented by a vector constructed by the circle diagram indicated in the figure. (See derivation in Appendix.) Note that, in general, *the deflecting force is not in line with the deflection*, therefore it has both radial and tangential components.



The tangential component of the deflecting force and the double-frequency variation in the static deflection are both unique characteristics of an unsymmetrical shaft. We find it convenient to use them in defining the "degree of dissymmetry" or "dissymmetry ratio," d, as follows

$$d = \frac{h}{c} = \frac{c_2 - c_1}{c_2 + c_1} = \frac{r_y}{y_{av}} = \frac{y_1 - y_2}{y_1 + y_2} \quad \ldots\ldots\ldots [1]$$

These ratios apply strictly to an ideally simple rotor; but the last two, being based on deflections, may be used as an approximate measure of dissymmetry for actual rotors.

THEORETICAL RUNNING CHARACTERISTICS

Normal critical-speed behavior (1–5) for ordinary round shafts is illustrated in Fig. 3, which shows graphs of amplitude and

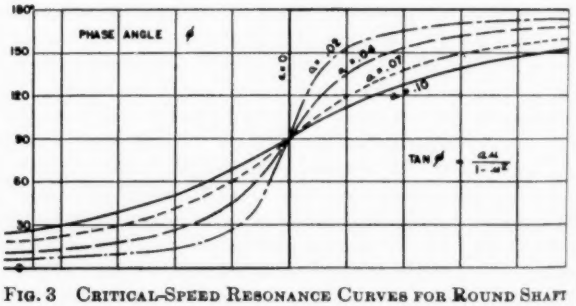


FIG. 3 CRITICAL-SPEED RESONANCE CURVES FOR ROUND SHAFT

phase angle plotted against speed. These are general resonance curves, based on the well-known expressions derived for an ideally simple rotor, slightly unbalanced and subject to linear damping. The amplitude r_y is proportional to the amount of unbalance, and is here plotted in units of the eccentricity E of the center of gravity. Speed u is on a relative basis, with the value 1.0 for the critical speed. The damping factor a, used as a parameter for the two families of curves, is also on a relative basis, as defined in the Appendix. Note that the peak amplitude at critical speed ($u = 1.0$) reaches a value which may be expressed quite simply as E/a; and that the corresponding value of the phase angle ϕ is always 90 deg.

For unsymmetrical shafts, corresponding critical-speed characteristics have been determined by an analysis given in the Appendix. From this, it appears that, subject to a certain condition, *the amplitude of the shaft may become infinite*, in spite of the presence of damping. The condition for infinite amplitude is simply that the degree of dissymmetry should be larger than the degree of damping, or $d > a$. For a shaft with moderate dissymmetry ($d < a$), there is apparently no infinite amplitude, but a number of other peculiarities. Thus we have two classes of unsymmetrical shafts to consider: One with moderate dissymmetry ($d < a$); the other with pronounced dissymmetry

($d > a$), for which the analysis indicates shaft amplitudes going to infinity.

Taking first the case of moderate dissymmetry, a set of typical resonance curves is given in Fig. 4. In contrast to Fig. 3, these are drawn for only a single value of the damping constant ($a = 0.07$). Curves for the corresponding round-shaft case are in short-dash lines for comparison. Note the importance of a new variable, the orientation angle (δ) of the center of gravity. The peak amplitude of vibration apparently varies by five to one on a rotor running with the same amount of unbalance over the same speed range, with the same damping and the same degree of dissymmetry and with changes only in the angular position of the unbalance. The highest peak appears when the unbalance is 45 deg ahead of the weak axis, in the direction of rotation; and the lowest peak, when the unbalance is 45 deg

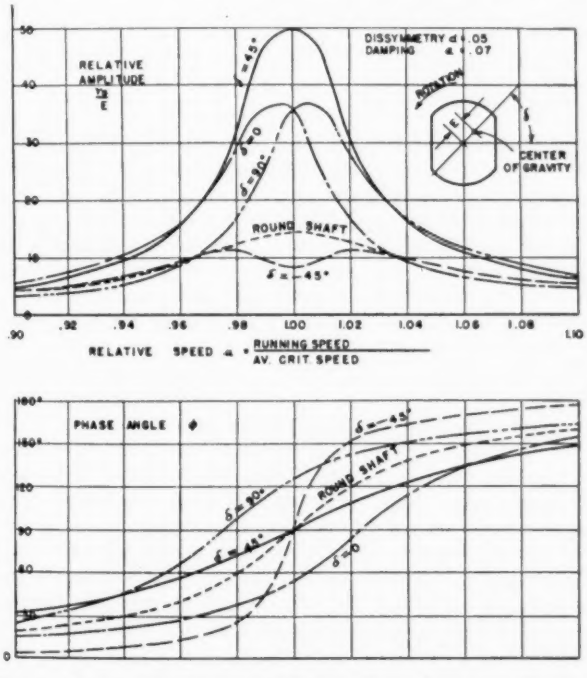

FIG. 4 RESONANCE CURVES FOR SHAFT WITH MODERATE DISSYMMETRY

behind this axis ($\delta = -45$ deg). This suggests the use of a polar diagram, Fig. 5, to show the variation of the peak amplitude with the angle of unbalance. This amplitude, it appears, may vary considerably with the direction of rotation since the most sensitive point for unbalance (45 deg ahead of the weak axis) becomes the least sensitive (45 deg trailing) if the rotation is reversed. Going back to Fig. 4 for a moment, some other peculiar effects of dissymmetry may be pointed out. The amplitude curves for the cases where the unbalance comes directly on the weak axis or the stiff axis ($\delta = 0$ or 90 deg) are somewhat distorted. It will be noted that in these cases the phase angle is materially different from 90 deg at the peaks of the amplitude curves.

Now, let us consider the case of pronounced dissymmetry ($d > a$) for which infinite peaks of amplitude are indicated. Fig. 6 is similar to Fig. 4, except for the increased dissymmetry ($d = 0.09$). It will be noted that the amplitude curves all show infinite peaks at two speeds. For zero damping, these peaks would correspond to the natural frequencies of transverse vibration in the planes of the weak and stiff axes, respectively; but with damping, they are moved closer together, until they merge into one infinite peak when $a \doteq d$. Operation between the two peaks has been shown to be unstable. The phase-angle curves show much the same peculiarities as in Fig. 5, except that in the case of unbalance at 45 deg behind the weak axis (the position of least sensitivity for the region of finite peaks)

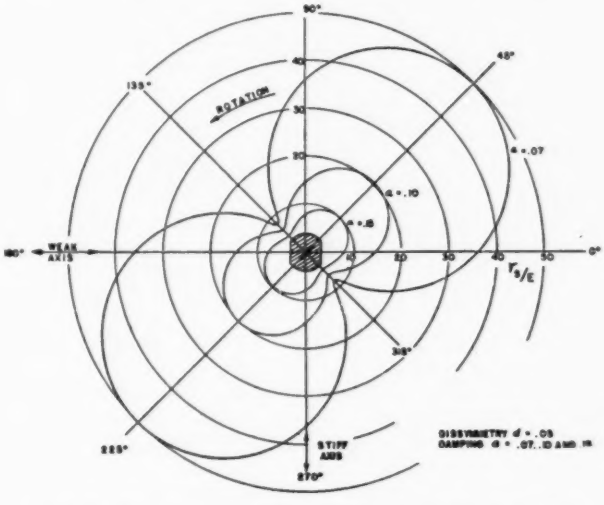

FIG. 5 AMPLITUDE VS. ANGULAR POSITION OF UNBALANCE

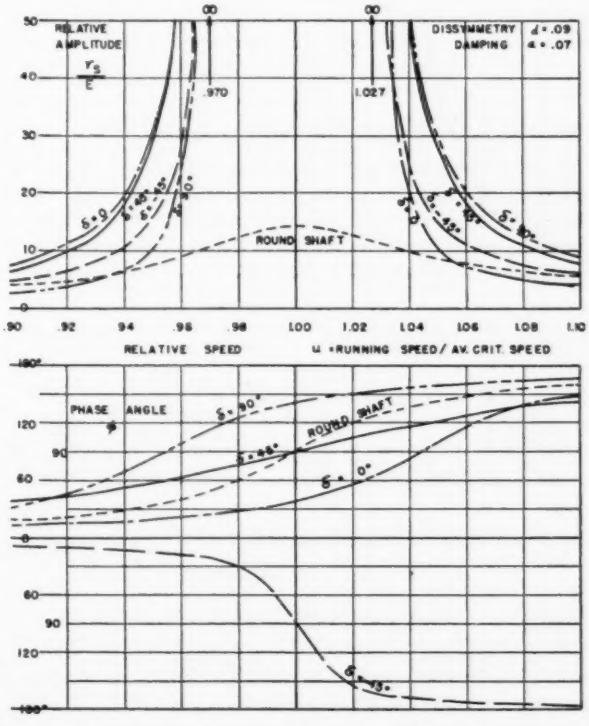

FIG. 6 RESONANCE CURVES, RELATIVELY LARGE DISSYMMETRY

the phase angle seems to be negative. That is, the deflection would seem to lead the unbalance instead of lagging behind it.

From a practical point of view, the theoretical effects of dissymmetry on the amplitude/speed curve of an ideally simple rotor may be simply shown as in Fig. 7. Here the lower dotted curve ($d = 0$) applies to a round shaft slightly out of balance, with moderate damping, over a speed range from 0 to 20 per cent above critical. The dot-dash curve ($d = 0.05$) shows the

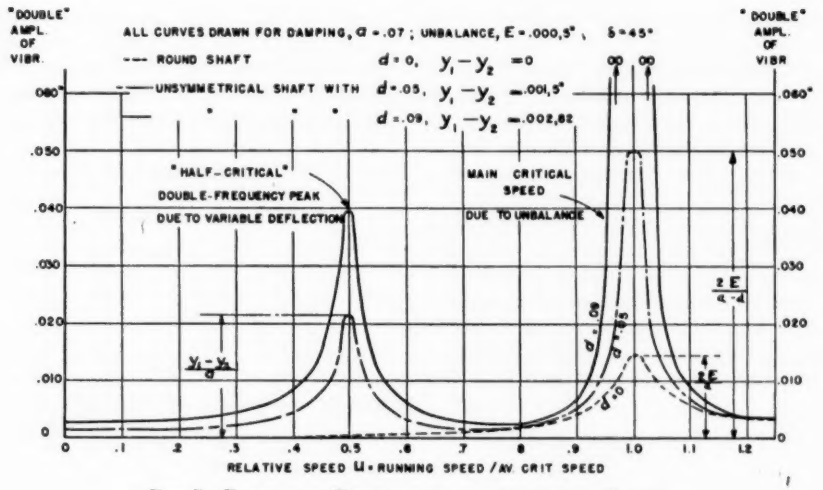

FIG. 7 EFFECTS OF DISSYMMETRY ON AMPLITUDE CURVE

effects of moderate dissymmetry, and the solid curve ($d = 0.09$) those of rather large dissymmetry, both with the unbalance located at the worst angular position ($\delta = 45$ deg). The critical-speed peak is increased materially by the moderate dissymmetry, and opens out to infinity with the larger dissymmetry. A double-frequency disturbance is also present (horizontal shaft assumed) with a resonant peak at half the critical speed, as previously mentioned. The amplitude of this vibration is determined by the variation in the static deflection of the shaft, just as the critical-speed vibration is proportional to the unbalance eccentricity E.

DESCRIPTION OF TEST SETUP

These theoretical indications were tested recently in the General Electric shops by means of a special setup with a rotor weighing 5300 lb, arranged as shown in Fig. 8. The span of this rotor was 10 ft 6 in. from center to center of bearings, and the main part of the shaft was $7^3/_4$ in. diameter. The bearings were

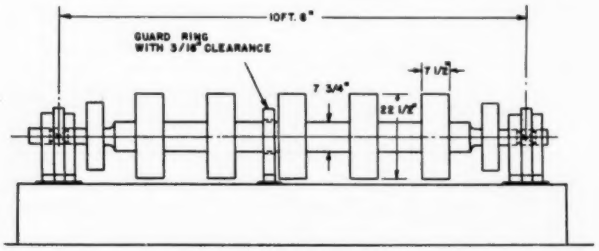

FIG. 8 TEST ROTOR SETUP

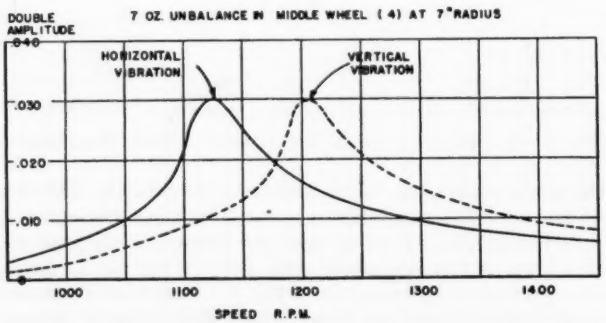

FIG. 9 AMPLITUDE CURVES OF THE TEST ROTOR WITH ROUND SHAFT

4 in. diameter by 5.25 in. long, ball-seated, and mounted in sturdy steel pedestals which were well anchored in a concrete block poured directly on the iron testing floor. The calculated critical speed (with round shaft) was 1200 rpm. For the sake of safety a guard ring was provided consisting of a dummy pedestal lined with a ring of leaded bronze, bored to a diametral clearance of $^3/_{16}$ in. over the shaft. The drive was by means of a flexible coupling from a dynamometer rated 200 kw at 4000 rpm, with Ward-Leonard speed control from a motor generator set. Vibration-amplitude readings were made with a weighted Starrett dial indicator held manually against a wooden "shaft stick" used to pick up the vibration from the shaft.

Preliminary tests were made with the shaft round to establish normal characteristics and particularly to determine the damping constant. This was needed so that the main test program could be planned to include two degrees of dissymmetry—one a little less than the damping, the other a little greater. The first step, of course, was balancing, which was carried out to a high degree of precision, such that the rotor would run gradually through critical speed with not more than 0.001 in. amplitude on the shaft.

Runs were then made with the rotor thrown out of balance by definite amounts, giving data such as shown in Fig. 9. It is interesting to note that the vertical peak checks the calculated critical speed, 1200 rpm, whereas the horizontal one comes at a lower speed, 1125 rpm. This, of course, is common experience with heavy rotors, even when set up solidly, as this one was. From these data, it was concluded that the effective damping constant a for the test setup was about 0.07. Space limitations do not permit giving the details of this determination. For the main test program, it was decided to "flat" the shaft sufficiently to make the degree of dissymmetry about 0.05 as a first step, and 0.09 as a second. Flats measuring $6^3/_8$ in. between faces were therefore cut on the $7^3/_4$ in. portion of the shaft. for the first step; and later these flats were cut down to $6^1/_4$ in. The resulting variation in the static deflection was in each case measured as a check, which agreed closely with the values anticipated.

TESTS WITH UNSYMMETRICAL SHAFT

Results from critical-speed tests carried out with the first step of "flatting," giving an apparent dissymmetry ratio of about 0.05, are shown in Figs. 10, 11, and 12. The first of these shows curves of vibration amplitude versus speed for several angular orientations of the unbalance with respect to the

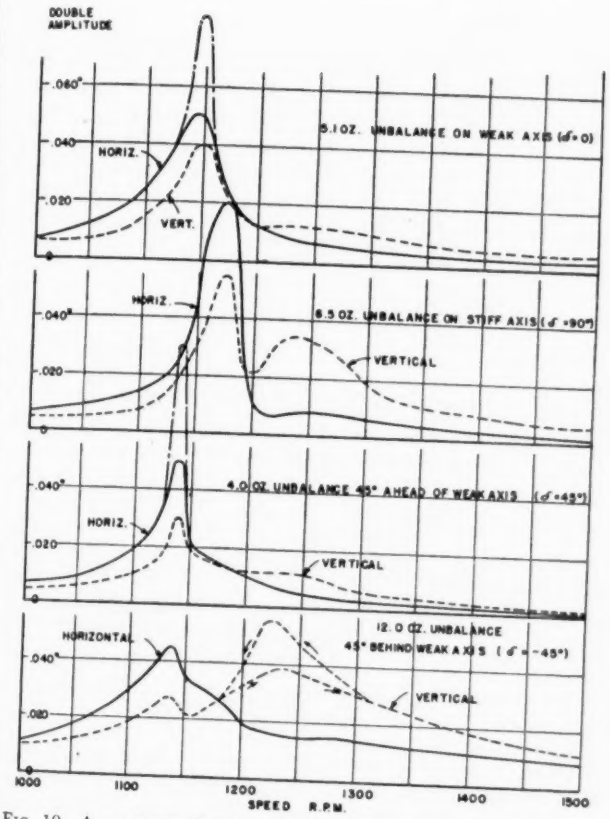

FIG. 10 AMPLITUDE CURVES OF THE TEST ROTOR WITH 6⅝-IN. FLATS ON SHAFT

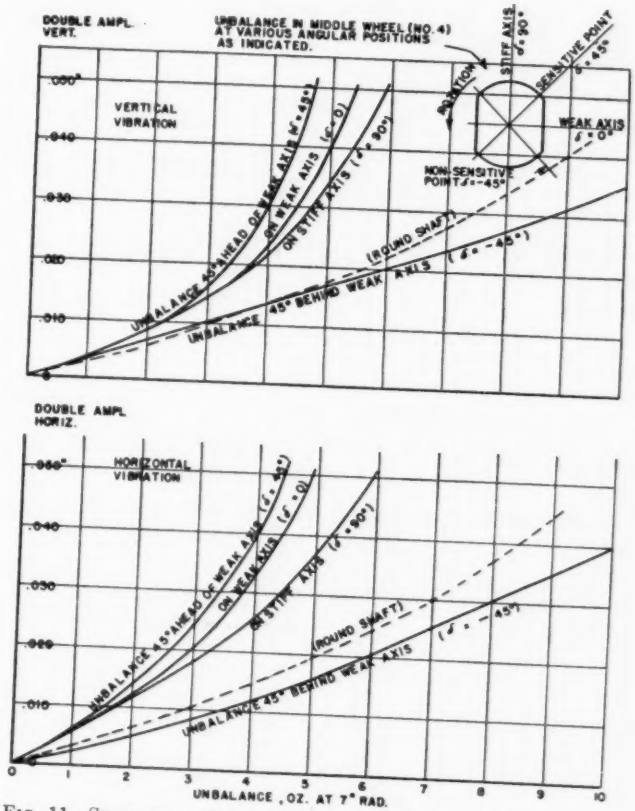

FIG. 11 SENSITIVITY CURVES OF THE TEST ROTOR WITH 6⅝-IN. FLATS ON SHAFT

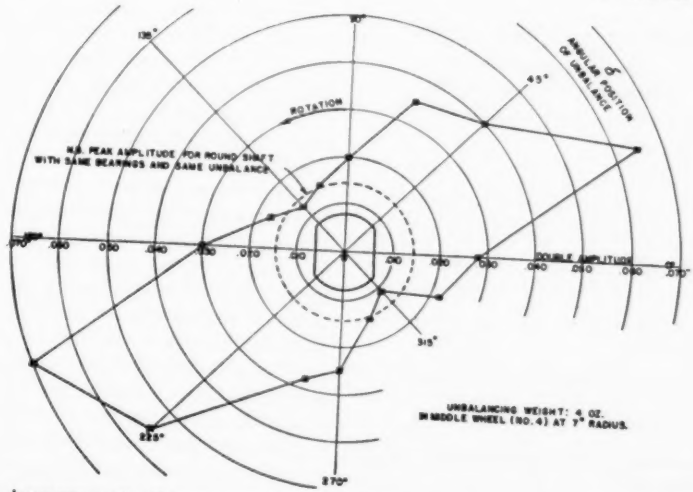

FIG. 12 PEAK AMPLITUDE VS. POSITION OF UNBALANCE FOR TEST ROTOR WITH 6⅝-IN. FLATS ON SHAFT

weak axis. In each case, the amount of the unbalance was enough to give fairly large amplitudes. For each of these angular positions, various sizes of unbalancing weights were tried in a series of runs. The peak amplitudes are plotted against the amount of unbalance in Fig. 11, as "sensitivity curves." The dotted curves here apply to the original round shaft. It is seen that three of the curves show greater sensitivity than for the round shaft—the fourth slightly less. The maximum sensitivity is apparently associated with a position about 45 deg ahead of the weak axis, and the minimum, about 45 deg behind, in accordance with theoretical indications. This is shown more clearly in Fig. 12, which represents in polar form the peak amplitudes obtained from another series of runs in which a 4-oz unbalancing weight was tried successively in each of 16 angular positions equally spaced around the middle wheel. Fig. 12 may be compared with the outside curve in Fig. 5. It may be noted that the shapes are not exactly similar, and yet the test rotor does actually show a 5/1 variation in sensitivity, depending only on the angular position of the unbalance. Also the positions of maximum and minimum sensitivity agree very well

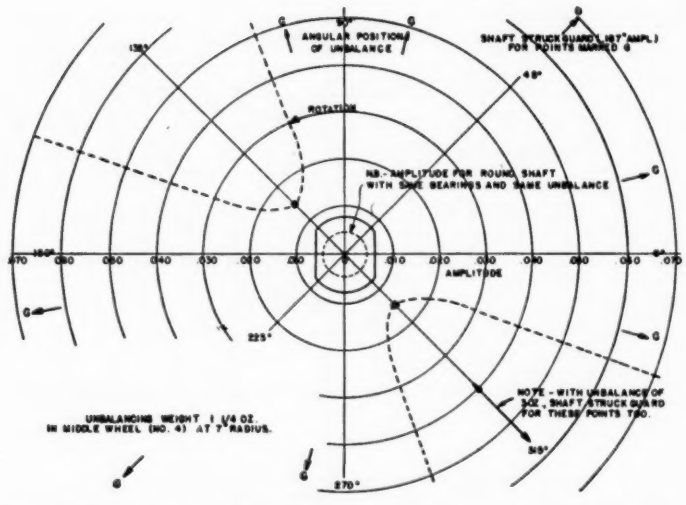

FIG. 13 PEAK AMPLITUDE VS. POSITION OF UNBALANCE FOR TEST ROTOR WITH 6¼-IN. FLATS ON SHAFT

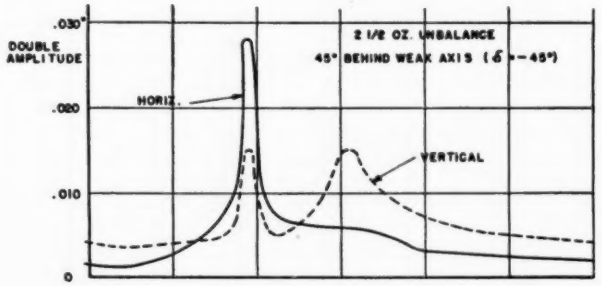

FIG. 14 AMPLITUDE CURVES FOR TEST ROTOR WITH 6¼-IN. FLATS ON SHAFT

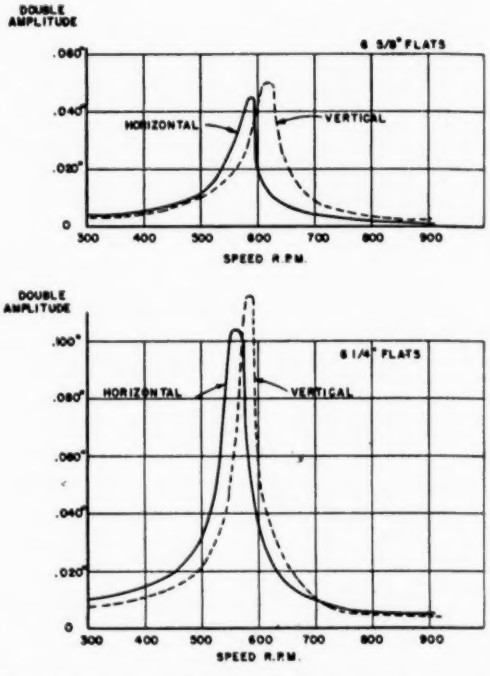

FIG. 15 DOUBLE-FREQUENCY PEAK OF VIBRATION AT HALF OF CRITICAL SPEED

with those theoretically indicated. As a matter of interest, reversed-rotation runs were made with unbalance at one of the 45-deg positions; they demonstrated an equally striking variation in sensitivity with the direction of rotation.

Considerable difficulty was encountered in securing the fine degree of balance prerequisite to the foregoing results. The good balance previously obtained for the round shaft had been spoiled in machining the flats, and rebalancing was necessary. The method used was systematic trial and error, based on critical-speed amplitude. Results were irregular, and it was finally necessary to make a great many runs with minor variations in amount and position of the weight in order to obtain a really close balance. The reason for the difficulty was of course that the critical-speed amplitude was no longer a good measure of the amount of "resultant" unbalance, but depended to a large extent on its angular position also.

When the shaft was flatted to 6¼ in. for the second step, to give $d = 0.09$, rebalancing was again necessary, and this time gave even more trouble than before. In fact, it was very nearly given up as hopeless, but after long-continued effort with very small changes, the rotor would finally run through the critical speed gradually with only 2 or 3 mils maximum amplitude.

The rotor was now so sensitive to a small unbalance that as little as 1.25 oz put on at any but the least sensitive positions (45 deg behind the weak axis) would cause the amplitude to build up at critical speed until the shaft actually rubbed on the guard ring. This building up of amplitude was at first gradual as the speed was increased little by little, but then more and more rapid until at a certain speed the shaft seemed to "shoot out" until it hit the guard. When this happened, the speed was immediately reduced, and the vibration would quiet down. Fig. 13 shows the results of trying this 1.25-oz weight at various angular positions. The shaft hit the guard, at 0.187 in. double amplitude, in every run except two—those in which the weight was located 45 deg behind the weak axis. The little circle at 0.0045 in. double amplitude shows the amplitude caused by the same unbalance on the same rotor before the shaft was flatted.

Greater unbalance was tried at these nonsensitive points, and it was found that 3 oz were sufficient to cause the shaft to build up and hit the guard ring even there. The maximum unbalance which could be safely carried at these points seemed to be about 2.5 oz. Amplitude-speed curves for this condition of unbalance are shown at the top of Fig. 14. The lower curves in the same figure show the results of an attempt to get corresponding curves for a 2.5-oz unbalance at one of the most sensitive positions, 45 deg ahead of the weak axis, by taking data as usual up to the point where the amplitude became excessive, and

then reducing speed enough to have the shaft quiet down again, with the idea that by using full power we could get rapid acceleration and possibly get past the critical-speed range before the vibration should become prohibitively rough; the purpose being then to take data above the critical range, and finally shut down again with rapid deceleration. This scheme did not work, as on rapid acceleration the vibration built up almost instantly to guard amplitude, and before the speed could be brought down again the shaft had rubbed heavily, producing much smoke and considerable heat distortion of the shaft. In spite of the fact that we had successfully run through the critical speed with rapid acceleration a few times with 1.25 oz of unbalance at the same position, it was felt that this was rather dangerous and it was not attempted again.

The double-frequency vibration associated with variable static deflection was conspicuous in all of these tests at speeds well below the main critical and, as expected, exhibited resonant peaks both horizontally and vertically at about half the corresponding main critical speeds. These are shown in Fig. 15 where the upper curves apply to the first step of flatting (d = 0.05) and the lower ones to the second step (d = 0.09). This double-frequency vibration became less and less noticeable at speeds above the range shown, being of no consequence at 1200 rpm and absolutely negligible at 2000 rpm and higher. The peak amplitudes for this "half critical" were not affected by changes in balance.

Summary and Conclusions

The peculiar vibrational characteristics of unsymmetrical shafts first pointed out by earlier writers have been further investigated both by an independent analysis and by tests on a special rotor representing a very large two-pole turbine-generator. Analysis and tests have agreed, even as to quantitative details, that shaft dissymmetry produces two important effects. First, a double-frequency disturbance is introduced, due to the variation in static deflection, which produces a peak of resonant vibration at about half the regular critical speed. Second, the normal behavior at the main critical speed is entirely upset, the sensitivity to unbalance being greatly increased and made a function of the angle at which the unbalance happens to lie on the rotor. In case of extreme dissymmetry, it appears that a rotor might prove to be unmanageable at critical speed.

As far as the writer knows, no difficulty of the second type has so far been experienced on commercial turbine generators, even of the largest sizes. And the double-frequency stator vibration noticeable on many of them disappears when excitation is removed, so that its source is magnetic rather than mechanical. The possibility of these mechanical difficulties seems very real, however, and full acquaintance with them should be of value to both designers and users. The obvious safeguard, since the damping factor is in general unknown, is to build high-speed machinery with a minimum of shaft dissymmetry.

Appendix

This appendix includes (*a*) an elementary derivation of useful expressions for the radial and tangential components of the force required to impress a given deflection on an unsymmetrical shaft; and (*b*) an analysis, based on the work of the late V. Petrovsky, for the motion of an ideally simple rotor consisting of a single heavy disk wheel mounted centrally on an unsymmetrical shaft, and running in rigidly supported bearings.

Radial and Tangential Components of Deflecting Force

Referring to Fig. 2, and the context of the paper, note that on resolving the deflection, $OS = r_s$, into components parallel and perpendicular to the weak axis, the corresponding components of the deflecting force are $c_1 r_s \cos \alpha$ and $c_2 r_s \sin \alpha$, as shown. Each of these may be resolved into radial and tangential components, which when added respectively give the total radial force

$$R = r_s (c_1 \cos^2 \alpha + c_2 \sin^2 \alpha) \quad [2]$$

and the total tangential force

$$T = r_s (c_2 - c_1) \sin \alpha \cos \alpha \quad [3]$$

Now introducing $c = (c_2 + c_1)/2$, and $h = (c_2 - c_1)/2$ we have

$$R = r_s (c - h \cos 2\alpha) \quad [4]$$

and

$$T = r_s h \sin 2\alpha \quad [5]$$

A similar derivation may be made for the gravity deflection diagram of Fig. 1, with results as shown.

Derivation of Equations for the Motion of an Ideally Simple Rotor With Unsymmetrical Shaft

Referring to Fig. 16, a section of the shaft adjacent to its mid-point is shown; the center point of this section is S, and

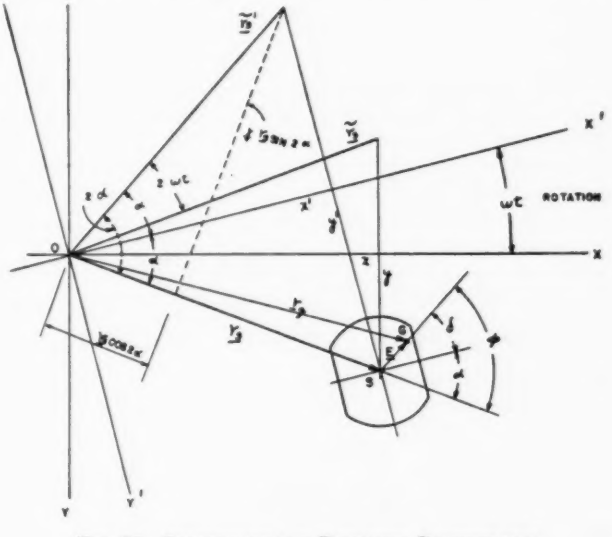

Fig. 16 Stationary and Rotating Coordinates

at the particular instant the lateral deflection of the shaft from the line of bearing centers O is represented by the radius vector, r_s. Rotation is indicated as counterclockwise at a constant speed ω. The unbalanced condition of the rotor is indicated by the fact that the center of gravity G is somewhat displaced from the shaft center S, the distance SG (or vector $\boldsymbol{E}$) representing the eccentricity. Two coordinate systems are shown: OX and OY are fixed coordinates; OX' and OY' are rotating coordinates such that OX' is always parallel to the weak axis of the unsymmetrical shaft. The orientation angles α, δ, and ϕ should be especially noted, α having the same significance as in Fig. 2, δ giving the fixed position of the unbalance with reference to the weak axis, and ϕ being the phase angle or "angle of lag." As such ϕ is usually measured backward from SG (CW), while it has been the author's choice to measure α and δ as positive when forward from the weak axis (CCW). Linear damping is assumed, equivalent to a single force opposing the motion of point S.

The first step toward setting up the equation of motion is the derivation of a vector expression for the deflecting force on the shaft, referred to the stationary coordinates. Note in Fig. 16, that the reflection of $\boldsymbol{r}_s$ in the rotating axis OX' is shown as $\bar{\boldsymbol{r}}_s'$, leading $\boldsymbol{r}_s$ by the angle 2α. Thus, $\bar{\boldsymbol{r}}_s'$ is parallel but opposite in direction to the vector shown as $h\boldsymbol{r}_s$ in Fig. 2. The deflecting force as a vector in rotating coordinates is therefore $(c\boldsymbol{r}_s - h\bar{\boldsymbol{r}}_s')$, where $c\boldsymbol{r}_s$ is the average radial component. Now note that the reflection of $\boldsymbol{r}_s$ in the stationary axis OX, indicated as $\bar{\boldsymbol{r}}_s$, is the same as $\bar{\boldsymbol{r}}_s'$ except for an angular difference of $2\omega t$. Hence, we may write $\bar{\boldsymbol{r}}_s' = \bar{\boldsymbol{r}}_s e^{j2\omega t}$, and the deflecting force becomes $(c\boldsymbol{r}_s - h\bar{\boldsymbol{r}}_s e^{j2\omega t})$. Actually, instead of the force exerted on the shaft, we shall use the opposite force $\boldsymbol{F}$ exerted by the shaft on the wheel, which is

$$\boldsymbol{F} = -c\boldsymbol{r}_s + h\bar{\boldsymbol{r}}_s e^{j2\omega t} \quad \ldots\ldots [6]$$

From this point on, the analysis may be simplified by dividing it into two parts, the first assuming the shaft to be vertical to eliminate the gravity effect which produces double-frequency vibration, and the second assuming the shaft horizontal but in perfect balance to eliminate the single-frequency vibration in the critical-speed range. In an actual horizontal shaft, of course, both forms of motion occur.

With the shaft vertical, we assume, in addition to the spring-constant force $\boldsymbol{F}$ given by Equation [6], a damping force $\boldsymbol{D}$ given by

$$\boldsymbol{D} = -b\dot{\boldsymbol{r}}_s \quad \ldots\ldots [7]$$

where $\dot{\boldsymbol{r}}_s$ represents the linear velocity of the shaft center S, and b is the ordinary type of damping constant, expressed as force per unit of velocity.

The mass of the rotor being taken as m, the equation of motion, in vector terms, is

$$\boldsymbol{F} + \boldsymbol{D} = m\ddot{\boldsymbol{r}}_g \quad \ldots\ldots [8]$$

Noting that $\ddot{\boldsymbol{r}}_g = \ddot{\boldsymbol{r}}_s + \ddot{\boldsymbol{E}} = \ddot{\boldsymbol{r}}_s - E\omega^2 e^{j(\delta+\omega t)}$
and substituting from Equations [6] and [7], there results

$$m\ddot{\boldsymbol{r}}_s + b\dot{\boldsymbol{r}}_s + c\boldsymbol{r}_s - h\bar{\boldsymbol{r}}_s e^{j2\omega t} = mE\omega^2 e^{j(\delta+\omega t)} \quad \ldots\ldots [9]$$

which is the differential equation to be solved.

A tentative solution is assumed, of the form

$$\left.\begin{aligned} \boldsymbol{r}_s &= \boldsymbol{Q}e^{j\omega t} \\ \text{with} \quad \boldsymbol{Q} &= X' + jY' \\ \text{and} \quad \widetilde{\boldsymbol{Q}} &= X' - jY' \end{aligned}\right\} \quad \ldots\ldots [10]$$

where X' and Y' are constants (for a constant speed) to be evaluated by substitution in Equation [9] for $\boldsymbol{r}_s$, $\dot{\boldsymbol{r}}_s$, etc. Expressions for X' and Y' are then found as functions of m, b, c, h, ω, E, and δ, which may be simplified by introducing the ratios u, a, and d for speed, damping, and dissymmetry by the following substitutions

$$\left.\begin{aligned} \omega &= u\sqrt{(c/m)} \\ b &= a\sqrt{(cm)} \\ h &= dc \end{aligned}\right\} \quad \ldots\ldots [11]$$

The scalar value of the deflection or half amplitude r_s is then found as $\sqrt{(X'^2 + Y'^2)}$ from which

$$\frac{r_s}{E} = \frac{u^2\sqrt{[(1-u^2)^2 + a^2u^2 + d^2 + 2d(1-u^2)\cos 2\delta + 2aud\sin 2\delta]}}{(1-u^2)^2 + a^2u^2 - d^2} \quad \ldots\ldots [12]$$

This is the desired general expression for amplitude in units of the eccentricity E.

The phase angle ϕ may also be determined from the values of X' and Y', on the basis that

$$\tan\alpha = \tan(\phi - \delta) = \frac{Y'}{X'} = \frac{(1-u^2-d)\sin\delta - au\cos\delta}{(1-u^2+d)\cos\delta + au\sin\delta} \quad \ldots\ldots [13]$$

These equations for amplitude and phase angle reduce to simpler forms for specific values of the unbalance angle δ such as 0, 45, 90, or 135 deg; and for zero dissymmetry ($d = 0$), reduce to the ordinary equations for the round shaft (see Fig 3).

Note that infinite amplitude is indicated if the denominator of Equation [12] is set equal to zero, which condition reduces to

$$u = \sqrt{\left[\left(1 - \frac{a^2}{2}\right) \pm \sqrt{\{d^2 - a^2 + (a^4/4)\}}\right]} \quad \ldots\ldots [14]$$

This indicates two speeds with infinite amplitude, if the expression under the second radical is positive; one such speed if it is zero; and unreal speeds if negative. The condition for having no infinite amplitude at any speed is then

$$d^2 - a^2 + (a^4/4) < 0$$

or

$$d < a\sqrt{[1 - (a^2/4)]} \quad \ldots\ldots [15]$$

With ordinary values of the damping constant a of the order of 0.10, it may be seen that the value of the radical may be taken as 1, with negligible error, so that to a close degree of approximation the condition for having no infinite amplitude becomes $d < a$.

* * * *

The double-frequency motion due to gravity will now be dealt with, on the assumption that the shaft is horizontal and in perfect balance, so that $E = 0$ (Fig. 16), point G coincides with S, and $\boldsymbol{r}_g = \boldsymbol{r}_s$. The force of gravity $\boldsymbol{W} = -j\boldsymbol{mg}$, must be taken into account, so that the equation of motion, in simplest terms, becomes

$$\boldsymbol{F} + \boldsymbol{D} + \boldsymbol{W} = m\ddot{\boldsymbol{r}}_g = m\ddot{\boldsymbol{r}}_s \quad \ldots\ldots [16]$$

from which

$$m\ddot{\boldsymbol{r}}_s + b\dot{\boldsymbol{r}}_s + c\boldsymbol{r}_s - h\bar{\boldsymbol{r}}_s e^{j2\omega t} + j\boldsymbol{mg} = 0 \quad \ldots\ldots [17]$$

For a tentative solution, it is assumed that, for any constant speed, $\boldsymbol{r}_s$ consists of a stationary vector $\boldsymbol{C}$, plus a rotating double-frequency vector $\boldsymbol{R}$, or

$$\left.\begin{aligned} \boldsymbol{r}_s &= \boldsymbol{C} + \boldsymbol{R}e^{j2\omega t} \\ \text{where} \quad \boldsymbol{C} &= X_1 + jY_1 \\ \text{and} \quad \boldsymbol{R} &= X_2 + jY_2 \end{aligned}\right\} \quad \ldots\ldots [18]$$

By substitution in Equation [17] for $\boldsymbol{r}_s$, etc., the values of X_1, Y_1, X_2, and Y_2 are determined. The amplitude of the double-frequency vector $\boldsymbol{R}$ is then found as $\sqrt{(X_2^2 + Y_2^2)}$.

Using the ratio substitutions given by Equation [11], we have

$$R = \frac{y_1 - y_2}{2}\,\frac{1 - d^2}{\sqrt{[(1-4u^2-d^2)^2 + 4a^2u^2]}} \quad \ldots\ldots [19]$$

For zero speed ($u = 0$), this expression reduces to $R = (y_1 - y_2)/2$, which is the "static whirl" illustrated in Fig. 1. The second term is a resonance factor, indicating that as the speed increases

the amplitude R builds up to a resonant peak when $(1 - 4u^2 - d^2) = 0$, or

$$u = 0.5\sqrt{(1 - d^2)} \quad [20]$$

Again, the radical may be neglected with ordinary values of d, of the order of 0.1, so that the double-frequency peak is found at about one half the critical speed as computed for the mean stiffness of the shaft.

Finally, the peak amplitude for the "half critical," with u as given by Equation [20] becomes

$$R_{peak} = \frac{(y_1 - y_2)/2}{a}\sqrt{(1 - d^2)} \quad [21]$$

in which again the radical term may ordinarily be neglected. This expression is remarkably similar to that for the peak amplitude at the main critical with no dissymmetry, $r_s = E/a$ (obtained from Equation [12], with $u = 1$ and $d = 0$). Equation [21] was used to check the value of the damping constant a during the tests described in the body of the paper, on the basis of the observed values of $(y_1 - y_2)$ and the amplitude at the half critical.

Discussion

Some Applications of Photoelasticity in Turbine-Generator Design[1]

ELMER K. TIMBY.[2] Progress in stress analysis and design is usually preceded by both analytical and experimental research aimed at the solution of certain hypothetical problems which attract the interest or curiosity of the investigator. Next, someone discovers that some of these ideal solutions are of practical importance and begins to use them in a rational manner. In the paper under discussion we see the happy result of an able research analyst and a practical designer applying methods largely perfected by himself to the satisfactory solution of a difficult problem. The author is to be complimented on the success of his investigations.

It is observed that the model used in finding the so-called "exact" stress-concentration factors for the segment-shaped transverse grooves in the two-pole generator rotor was studied while subjected to a pure bending moment, and consequently no shear. It is doubtful whether this condition exists in the rotor when in service. Undoubtedly the shear stress near the periphery of the rotor is low but is it not possible that shear might have some effect at the bottom of the rather narrow and widely spaced grooves?

Question number 1 then is: Is the author of the opinion that the observed stress-concentration factors would have been the same if the model had been subjected to a combination of transverse shear and bending moment?

With further reference to the rotor, the plane section selected for study was cut from the rotor along the axis of symmetry and at a point which included the deepest portion of the narrow transverse slots. Stress-concentration factors were observed for this location at the bottom of the slots. There is material near the ends of the slots considerably further from the axis than is the material at the bottom of the groove (about 20 per cent further in the rotor shown in Fig. 2 of the paper). It seems reasonable to suspect that failure could not occur at the bottom of the slot (13 in. from the axis) until the material at one end of a slot (15.5 in. from the axis, measured parallel to the 13-inch dimension, and not radially) had suffered considerable deformation or possibly failure.

Question number 2 may be stated as: Was a diametrical section including the ends of the slots studied? If so, what was the strength when compared to the one which was studied; and if it was not studied, why was it disregarded?

The second test describes the experimental determination of centrifugal stresses in the rotor.

It should be noted that K as computed for the core stresses by use of Equation [1] of the paper should be 1.31 instead of 1.13. This may be a misprint since the stresses appear to be correctly plotted in Fig. 5.

Turning now to the subject of stress concentrations in T-heads, it is noted that the author considered it inadvisable to load the specimen at any point closer to the shaft than about twice the radius of the fillet at the junction of head and shaft; and further that it is in this vicinity that the value of the stress-concentration factor is increasing most rapidly. The reason given for not applying the load at a point closer to the shaft is that the material underwent considerable distortion in the neighborhood of the concentrated supports which would probably lead to a false determination of the maximum stress. This reason appears sound, but it also appears to avoid the problem rather than to solve it. Although not recommended, it would have been possible to extrapolate the experimental curve of Fig. 7 to a value of infinity for k as easily as to a value of about 5.45. Furthermore, it is probable that in actual construction the point of support may be very close to the shaft unless the supporting material is purposely cut away to avoid such a condition.

The author states that tests have revealed that stress concentration at such fillets is usually much greater than what one could expect from a comparison with known results obtained with tension and bending specimens of similar fillet ratios.

Question number 3 follows: How reliable does the author consider the dotted portion of the curve for k as plotted in Fig. 7? And question number 4: Is it convenient for the author to explain how the stress-concentration factor is affected by the presence of a loaded boundary at the point at which the stress is to be determined?

While further discussing the matter of the location of the load on the flange the author expresses the belief that the case of simple axial tension corresponds to the location of the loads on the flanges at infinite distances on either side of the shaft. It is difficult for the writer to visualize the similarity between these two conditions of loading. In the case of simple axial tension there must be a plane, normal to the direction of the load, at the mid-depth of the head along which there is no shear and on which the normal stresses vary from some large value at the center line to lower values on either side. Also, from symmetry, there must be no resultant shear on planes parallel to the length of the shaft and located on either side of it. It is not evident that either of these conditions would be produced by loads placed at an infinite distance on either side of the shaft.

As the final question, number 5: What was the line of reasoning which led to the conclusion that the two loading conditions just mentioned were equivalent?

An attempt has been made in this discussion to ask the author to expand certain items which were treated in a brief manner in his original presentation. There has been no intention of questioning the reliability of the work. On the contrary, the author is to be congratulated for having made such distinct progress in the field of stress analysis.

M. M. FROCHT.[3] In 1934 the writer investigated factors of stress concentration at fillets subjected to the combined action of pure compression and bending using a scheme of loading as shown in Fig. 1 of this discussion. The results were incorporated in the paper "Some New Aspects of Stress Concentrations," presented before the American Association for the Advancement of Science at its meeting held in Pittsburgh, in February, 1934.

Fig. 2 of this discussion shows a typical stress pattern, while the writer's Fig. 3 represents a curve giving the factors of stress concentration for $R/d = 0.075$, the case investigated by Dr. Hetényi. It was found convenient to plot k against the ratio σ/σ_b in which

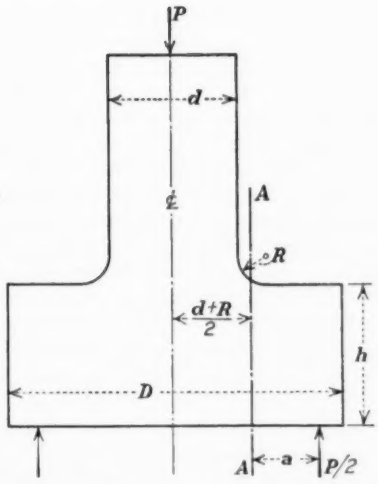

FIG. 1 FILLET SUBJECTED TO COMBINED PURE COMPRESSION AND BENDING

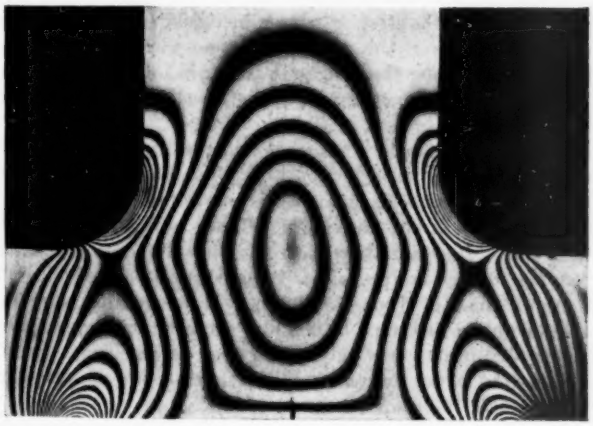

FIG. 2 TYPICAL STRESS PATTERN OF FILLET SHOWN IN FIG. 1

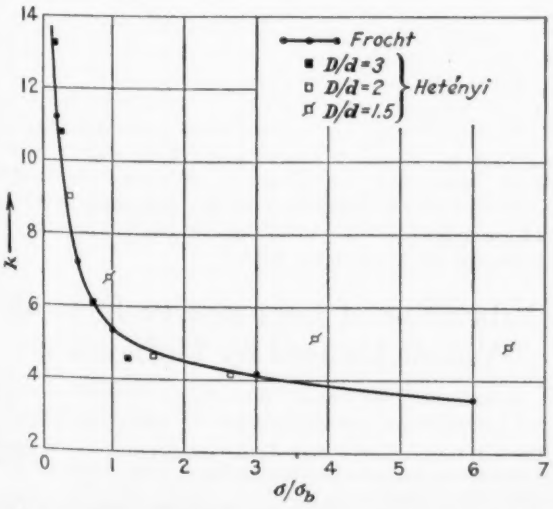

FIG. 3 STRESS-CONCENTRATION FACTORS FOR $R/d = 0.075$

σ and σ_b denote the compressive and bending stresses respectively. These two nominal stresses were calculated from the elementary equations

$$\sigma = \frac{P}{A} \quad \text{and} \quad \sigma_b = \frac{Mc}{I}$$

the bending stress σ_b being computed at section A-A distant $(d + R)/2$ from the axis, as shown in Fig. 1 of this discussion.

It is interesting to point out that all the data in the fifteen curves of Fig. 9 of the paper included in the range between $D/d = 1.8$ and $D/d = 3$ is contained in the single curve of Fig. 3 of this discussion. It would therefore seem that for T-heads in which D/d is not much less than 2, the local effect of the distributed loads can be neglected and factors of stress concentrations can be calculated on the basis of the ratio of direct to bending stresses.

Curves similar to that shown in Fig. 3 of this discussion are now available for a range of $R/d = 0.0572$ to $R/d = 1.00$. The writer hopes to find an opportunity to publish all of these curves in the near future.

A. L. KIMBALL.[4] The question has been raised as to whether the assumption of plane stress is adequate in solving the elastic problem of stress concentration produced by centrifugal body stress at a central hole in a revolving cylinder.

In the case of a thin disk, this assumption is evidently adequate where axial contraction is not restrained, but for a long cylinder revolving about its axis, considerable axial shear will arise because the cylinder is sufficiently long so that its central portions cannot contract axially relatively more than its peripheral portions do. Consequently, a more accurate solution can be obtained by assuming that no differential *strain* can exist along the cylinder axis, but that it be confined to the plane of the cylinder section only. In other words, whereas the assumption of plane *stress* gives a more accurate result in the rotating-disk problem, the assumption of plane *strain* gives a more accurate result in the case of the cylinder problem. These two cases are treated by Love.[5]

A comparison of these two theories shows that, other things being equal, for a small central hole the tangential stress comes out about 5 per cent higher for plane strain than for plane stress, whereas at the edge of the disk the former theory gives a tangential stress 25 per cent lower than the latter.

R. E. NEWTON.[6] The author not only made a judicious choice of problems, but also he has been decidedly realistic in his application of the photoelastic techniques. For example, in studying the problem of the stress concentration in transverse grooves of a rotor he has treated this problem as a two-dimensional one. The use of this simplification is highly desirable from an experimental point of view and the reference to Neuber's theoretical results leaves the reader with confidence in the validity of the approximation. The replacement of a distributed gravitational loading by a pair of externally applied couples seems also justifiable, but the author has neglected to point out the nature of this approximation.

The simplicity and effectiveness of the mounting used to study the centrifugal stresses around the bore are notable. Concerning the quantitative results of this analysis, it is interesting to note that the substitution of $\alpha = 1$ in Equation [1] gives a stress that

is almost exactly equal to the experimentally determined value of the maximum stress at the edge of the hole. This, of course, would correspond to the case of a winding having the same specific gravity as the rotor body.

The manner in which the variables of the T-head problem have been separated is highly commendable. Altogether too many sets of exhaustive data have been gathered in connection with similar problems, only to be presented in such a manner that they are almost useless to the practical designer.

W. M. MURRAY.[7] Although the paper[1] deals primarily with the problems of rotor design, it brings out two very significant points which are usually either taken for granted or neglected. The first of these involves the effect of adjacent stress concentrations. The effect of a single discontinuity is usually considered rather serious, and rightly so, but, as the author's Table 1 shows, several discontinuities adjacent to one another tend to give a lower value of the stress-concentration factor than the single discontinuity. This is borne out in practice in the cases of threaded connections which stand up in spite of their form where evidently the adjacent threads tend to break down the concentrations.

The problem of the stress concentration at the fillet in the head of a bolt is exceedingly interesting and suggests the possibility of the use of an internal fillet to relieve the stress condition. In the cases of the concentrated loads being applied to the T-heads, it is evidently desirable that the point of application of the load should be at about $d/2$ from the shank. In this case the concentration factor for the author's problem would be about 3.25. Provided that the load is concentrated, the area required to support it will be small so that there would be a good opportunity to use an internal fillet of even larger radius than that considered in the present example. Provided that the head of the bolt is sufficiently thick to make the effect of bending negligible, the internal fillet would not produce a weakening effect and at the same time it would insure that the load could not be applied nearer to the shank than a distance of $2R$, where R is the fillet radius. In the case of the distributed load, about the same conditions would prevail as for the concentrated load with the exception that the presence of the internal fillet would necessarily reduce the bearing area to some extent. The writer feels that entirely too little attention is paid to the use of the internal fillet and that stresses in bolt heads might be reduced through its use, although the cost of manufacture possibly would be increased.

AUTHOR'S CLOSURE

The five questions raised by Professor Timby will be answered in the same sequence as they were given.

The shearing force due to the distributed weight of the rotor will be in any case small around the middle of the span of the rotor where the maximum normal stress from bending occurs. For this reason, it seemed sufficient to test the models in simple bending.

It is true that the nominal bending stress will be higher in the extreme fibers of vertical sections to the right or left of the symmetry section which has been investigated. However, such an increase of the nominal stress will be small in comparison to the decrease of the concentration factor, due to the lesser depth of the grooves in these sections. Taking the extreme case, which is a longitudinal section through one end of the transverse grooves, we will have a nominal stress only about 20 per cent larger than in the symmetry section while, at the same time, the k factor, because of the vanishing grooves, will approach a value of unity. This shows that we must look for the maximum stress value in the axial symmetry section at the deepest point of the grooves.

[7] Instructor in Charge of Photoelasticity, Massachusetts Institute of Technology, Cambridge, Mass. Mem. A.S.M.E.

The author is obliged to Professor Timby for pointing out that the correct value of the k factor in the centrifugal-stress problem is 1.31 instead of 1.13, being a ratio of 85.4 to 65.2.

The dotted portion of the curve in Fig. 7 of the paper aims merely to show the subsequent increase of the concentration factor as the load approaches the fillet. Professor Timby is right in saying that one could just as well assume a singular point with an infinite k value at the point where the straight horizontal boundary joins the fillet. In practical cases, however, the load is always more or less distributed and a singular value would not alter the area along the loaded portion under the influence line, like the one in Fig. 7. At this point, it might be well to call attention to the fact that the mean value of the k ordinates in Fig. 7 is 3.5, the same as the one obtained by a uniformly distributed loading along the flanges of a T-head of the same proportions as shown in Fig. 9.

The subject of the fourth question, namely, the determination of the principal stresses at a loaded boundary, constitutes a separate problem which also can be analyzed photoelastically. Such a problem, however, did not come up in the present T-head tests where the maximum stress is always in the curved part of the fillet, the boundary of which naturally is free from external loading in any case.

The fifth question is probably due to a misunderstanding. The statement, that the stress condition in T-heads subjected to simple axial tension is the same as if the same sample were to be supported along the flanges at points in infinity, referred to T-heads of very large depth (e.g., the one in Fig. 7), where the bending of the flanges is negligible.

Due to the particular scheme of loading which Professor Frocht used, his concentration factors were obtained merely from the bending action in the flanges which is only one of the three sources of the increase in fillet stresses at T-heads as was pointed out in the paper. It was gratifying to find that, for cases where the bending stresses are prevalent, the author's results check with those obtained by Professor Frocht. However, this comprises only one phase of the problem and a complete solution could be represented in any case only by a set of curves, irrespective of whether the factors are referred to a nominal σ stress value or to σ/σ_b ratios of Professor Frocht.

Mr. Kimball's discussion gave further evidence in support of the fact that the core stresses due to the inertia forces in a revolving cylinder can be determined with satisfactory accuracy from plane-model tests.

The fact, pointed out by Mr. Newton, that the substitution $\alpha = 1$ in Equation [1] gives almost exactly the value of the maximum stress at the core, is undoubtedly only a curious coincidence and could not serve as a general rule.

The author agrees with Dr. Murray's statement that in some cases the application of internal fillets might reduce substantially the peak stress value. In order to be able to suggest the best design for a particular case, however, one must know the effect of all the variable proportions in T-heads. This could be achieved only by a systematic study of all the variables in a manner similar to the one advanced in the paper.

Vibration of Locomotive Driving Wheels Caused by Unbalance[1]

R. EKSERGIAN.[2] This paper[1] represents a clear-cut condensation of a complicated research problem in counterbalancing that

[1] By O. J. Horger and C. W. Nelson. Published in the December, 1939, issue of the JOURNAL OF APPLIED MECHANICS, Trans. A.S.M.E. vol. 61, 1939, p. A-177.

[2] Consulting Engineer, Edward G. Budd Mfg. Company, Philadelphia, Pa. Fellow A.S.M.E.

has confronted the railways in the high-speed operation of steam locomotives.

The actual problem is complicated with a system having several degrees of freedom, while the disturbing forces include, in addition to the unbalance in the driving wheels, the effect of a mutual vertical reaction and torque reaction between the drivers and spring-borne parts and a varying tractive force at the drivers and correlated drawbar pull resulting in additional couples on the system. In a first approximation, the dynamic system consists of a two-mass system, the spring-borne parts, and the driving wheels separated by the spring suspension, while the drivers in turn are supported by the elastic rail spring. If all the drivers had the same mass and the unbalance force per driver was the same, the system can be considered as an inverted double pendulum with two degrees of freedom. Actually a better approximation is a system consisting of the spring-borne parts, and a parallel system with individual driving masses and trucks, so that, from a coplanar aspect, we have the number of degrees of freedom equal to the displacements of these masses, with an additional degree of freedom for pitching of the locomotive chassis. But the crosswise motion on roll of the chassis and individual driving wheels adds further degrees of freedom. Finally, to further complicate matters the spring suspension is tied in by equalization of the running gear. This reduces the degrees of freedom and throws us back in a first approximation to a double pendulum for coplanar motion.

On the basis of a double-spring pendulum the displacements of the driving wheel and spring-borne mass (per driver), for the steady state, are as follows. For the driver

$$x_1 = \frac{P_D\,(k - \omega^2 m_2)}{(k_R + k - \omega^2 m_1)\,(k - \omega^2 m_2) - k^2} \quad \ldots\ldots [1]$$

For the spring-borne mass

$$x_2 = \frac{P_D k}{(k_R + k - \omega^2 m_1)\,(k - \omega^2 m_2) - k^2} \quad \ldots\ldots [2]$$

so that the ratio of the motion of the spring-borne parts to that of the driver is

$$\frac{x_2}{x_1} = \frac{k}{k - \omega^2 m_2} = \frac{1}{-(\omega^2/p^2) + 1} \quad \ldots\ldots [3]$$

Now p, the natural frequency of the spring-borne parts with rigid rail, depends only on the static deflection of the driving springs. With a spring constant 10,500 lb per in. and a spring weight of 24,000 lb per wheel, then δ = (spring deflection) = 2.3 in., approximate. Hence, $p/2\pi = 2.06$ vibrations per second or roughly 120 per minute. With operating speeds around 360 rpm this means $x_2/x_1 = -1/8$ and becomes less with increasing speeds. Therefore, the authors' assumption of neglecting the motion of the spring-borne parts is well-founded. Thus, on the basis of coplanar motion, the motion of the driving wheel practically operates as a system with one degree of freedom.

In locomotive-driving-axle assembly the unbalanced applied forces, the spring reactions, and rail reactions are considerably out of plane, though symmetrical to the center line. While the authors have considered the problem as a vibration in a single plane the writer suggests a little greater refinement by including the entire axle assembly. Proceeding with the assumption made by the authors that the motion of the spring-borne parts, compared with the motion of the axle assembly, is small, then for the axle assembly in vibrating in the pedestal guides, we have a system with two degrees of freedom, defined by the vertical coordinate y_g and the angular coordinate θ in the transverse plane. Let G = lateral distance between the elastic rail supports with spring constants k_R and a = lateral distance between spring supports, with spring constant k. Let m = total mass of axle assembly and ρ = the radius of gyration in rotating about a horizontal axis at the center in a transverse plane.

The spring reactions are $k[y_g + (a/2)\theta]$ and $k\,[y_g - (a/2)\theta]$ for either side. The elastic rail reactions are $k_R[y_g + (G/2)\theta]$ and $k_R[y_g - (G/2)\theta]$. Assume the unbalance to be concentrated in the wheel planes or at any lateral distance L apart. Let P_D = the dynamic unbalance = $W_0/g\ \omega^2 R$. Since the cranks are at quadrature and the unbalance is usually spread at an angle greater than $\pi/2$, the applied forces are $P_D \sin \omega t$. For the right wheel and $P_D \sin(\omega t - \beta)$ for the left wheel, where $\beta = (\pi/2) + \alpha$.

Then, for the vertical translation

$$m\ddot{y}_g = -2(k + k_R)y_g + P_D\,[(\sin \omega t + \sin(\omega t - \beta)]\,. \quad [4]$$

and for the angular motion

$$m\rho^2\ddot{\theta} = -2\left[\frac{ka^2}{4} + \frac{k_R G^2}{4}\right]\theta + P_D\left[\frac{L}{2}\sin \omega t - \frac{L}{2}\sin(\omega t - \beta)\right] \quad \ldots\ldots [5]$$

where it is to be observed no coupling between the two motions occurs due to symmetry and equality of the spring constants for either side.

Then, for steady-state condition

$$y_g = \frac{P_D[\sin \omega t + \sin(\omega t - \beta)]}{(p_1^2 - \omega^2)\ W/g} \quad \ldots\ldots [6]$$

$$\theta = \frac{P_D(L/2)[\sin \omega t - \sin(\omega t - \beta)]}{(p_2^2 - \omega^2)\ W\rho^2/g} \quad \ldots\ldots [7]$$

where $m = W/g$.

On the basis of the authors' criterion on lifting from the rail, we must equate the deflection $y_R = y_g + (G/2)\theta$ to $(S + W)/(2k_R)$ where W and S now refer to the entire axle assembly and spring weight per driver.

On combining Equations [6] and [7], we have

$$y_R = \frac{RW_0}{W}\left[\frac{\omega^2}{(p_1^2 - \omega^2)} + \frac{GL}{4\rho^2}\,\frac{\omega^2}{(p_2^2 - \omega^2)}\right]\sin \omega t \quad \ldots\ldots [8]$$

$$+ \frac{RW_0}{W}\left[\frac{\omega^2}{(p_1^2 - \omega^2)} - \frac{GL}{4\rho^2}\,\frac{\omega^2}{(p_2^2 - \omega^2)}\right]\sin(\omega t - \beta) \quad \ldots\ldots [9]$$

where

$$p_1^2 = \frac{2(k + k_R)g}{W}, \qquad p_2^2 = \frac{(ka^2 + k_R G^2)g}{2W\rho^2}$$

While this analysis does not disclose any further characteristics than given by the authors, it does permit a simpler analysis of the effects of the unbalance since in place of $P_D \sin \omega t$ and $P_D \sin(\omega t - \beta)$ we can consider all the unbalance centrifugal forces for the vertical motion by simply summing up their vertical components disregarding their planes of action, and for the angular motion summing up their moments about the center of axle to their respective planes of action. Moreover, the planes of action of the spring forces and rail reactions are properly taken into consideration.

By considering the general solution which includes the free motion, we have the four constants for determining the motion in the second phase when either or both wheels are off the rail and the corresponding rotational angle for this period.

Perhaps the most serious error in both the authors' and the writer's analysis is the disregard of the very large friction damping in the plate springs. The initial friction in locomotive plate

springs may be in the order of 10,000 lb. Due to the large spring constant of the rail, the equivalent friction of the rail spring may not enter materially in the problem.

Since the spring systems of locomotives with inside journals are not likely to be modified, nor the proportions of driving wheel and spring-borne parts and rail conditions, the solution of eliminating serious vibration of locomotive driving wheels appears in reducing the unbalance to a minimum. The Timken Company, through Dr. Horger and Mr. Buckwalter should be congratulated in making this possible through excellent technical design of lightweight rods and reciprocating parts.

ALEXANDER W. LUCE.[3] "This paper is an extremely interesting one, and presents some matters which have been but very little understood, and which appear to be of very great importance in the operation of railroads. The fact that a locomotive driving wheel in ordinary service actually rises entirely clear of the track at high speeds is a matter of so much importance that it certainly should receive great attention from The American Society of Mechanical Engineers." Thus opened a discussion of two papers[4] on counterbalance and rail pressures at the December, 1894, meeting of the Society. Present readers will find them most interesting reading because of the revelation in the present paper of progress in means for investigation, both physical and mathematical. Ample evidence of the seriousness of the problem is presented throughout the former papers as well as in the present one. Comparison of the papers will disclose how the worst reciprocating weights of yesterday were not as bad as the best of today.

The authors are to be congratulated on having adapted recent progress in photography to a problem that Professor Goss undertook to solve by calipering wire rods passed under the drivers of a locomotive on the test stand at Purdue University, and on their use of the advances made in recent years in the mathematical treatment of vibrations. The authors of forty-five years ago spoke of vibrations, oscillations, track stiffness, and spring stiffness, but it has remained for the present authors to handle these factors with confidence.

A further interesting fact is that the Burlington road is prominent in both the former and present papers.

AUTHORS' CLOSURE

Dr. Eksergian's use of two coordinates to express the motion of the axle assembly indicates one of the refinements which can be introduced into the authors' analysis without unduly complicating the problem. During the preparation of their paper, the authors considered this refinement but did not use it because it would not be expected to affect their numerical results greatly, particularly for vibrations such that the wheel did not leave the rail, and because calculation of ρ, the radius of gyration of the axle assembly about an axis through its center of gravity and parallel to the track center line, would be laborious for an actual locomotive.

The authors agree with Dr. Eksergian that the neglect of friction constitutes one of the most serious approximations in their analysis. The need for data concerning the friction forces was emphasized in the authors' paper. However, this and other assumptions in the authors' analysis, such as the neglect of the effect of one driver on vibrations of the other drivers and the neglect of the effect of angularity of the main rod, were necessary if the problem was to be kept simple enough for numerical calculation to permit a better appreciation of the fundamental aspects of the problem. It should be mentioned that operation of a locomotive with too short a cut-off will cause the main drivers to lift from the rail at speeds lower than those reported in the paper due entirely to the vertical component of the steam force transmitted to a main driver by the main rod. This possibility should not be ignored. However, the authors have tried for the most part to focus attention on the effect of overbalance which may be considered of fundamental importance in connection with rail damage observed in service.

The authors agree that the two papers[4] referred to by Professor Luce make most interesting reading. The experiments described in the paper by Professor Goss demonstrated the possibility of a driving wheel lifting and indicated that the maximum lift of a driving wheel lags behind the maximum upward force. The tests by Professor Goss do not detract from the value of the test results given in the authors' paper since his tests were made on a test stand which probably represented a nearly rigid foundation instead of comparatively flexible track. If the foundation under the test stand did have a flexibility comparable to that of a railroad track, then the test conditions were still complicated by the presence, between this foundation and the locomotive drivers, of a large mass consisting of an axle, two supporting wheels, brakes, and other attachments. The advantages of the photographic method described by the authors are principally that (1) it can be used in tests made on actual track either with or without slipping, (2) it is possible to observe the lifting of the wheel during a number of consecutive revolutions, and (3) it is possible to observe not only the motion of the wheels but also the approximate deformations of the rail.

The authors have a few comments to add and some acknowledgments to make concerning the theoretical work in the paper[4] by D. L. Barnes. Mr. Barnes referred to a still earlier paper[5] by R. A. Parke. In his paper, Mr. Parke arrived at the differential equations[6] of motion for a driving wheel on or off the rail. For steady-state motion on the rail, Mr. Parke obtained Equation [2] and the three preceding equations.[7] For motion of sufficient amplitude so that the wheel was off the rail during part of a revolution, Mr. Parke did not consider the constants of integration, specifically A and B in the authors' Equation [1] and two other constants in the equation for x_2. For this reason, Mr. Barnes stated in his paper[8] that "later Mr. Parke found that his analysis did not take into account all of the conditions . . . . . ." Mr. Parke did not examine carefully the significance of his equivalent of the authors' Equation [2]. Due to the form in which he left this equation, he arrived at the erroneous conclusion, "it is evident that a wheel is more easily lifted from a rigid than from an elastic track," meaning that less overbalance would be required to produce lifting at a given speed for rigid track than for comparatively flexible track. Actually Equation [2] shows the opposite to be true except at speeds so low that $\omega < q$, using the authors' notations. At such speeds ridiculous values of overbalance are required to produce lifting. When $\omega = q$, the overbalance required to produce lifting is $\frac{(S+W)g}{R\omega^2} =$ 2680 lb for the locomotive constants given under Fig. 6 of the paper, and $U = 1500$ lb per sq in. Mr. Barnes showed in conclusion (g),[9] that he realized the error in Mr. Parke's conclusion.

In the paper[4] by Mr. Barnes, the theory of vibrations of a driving wheel was developed in an appendix by Professor J. B. Webb. The latter obtained equations which the authors have identified with Equation [1] for x_1 and the corresponding equation[10] for x_2. At this point Professor Webb and Mr. Barnes found that their mathematical difficulties were just beginning. Using the equations for x_1 and x_2, an attempt was made to determine whether or not the maximum lift should occur when the unbalance was directly up. They did not, however, assume a steady-state vibration but calculated the vertical motion of the wheel through 9 revolutions with "stupendous" labor, beginning with $x_1 = 0$, $\frac{dx_1}{dt} = 0$, at $\omega t = 90$ deg. Mr. Barnes concluded that "the maximum lift of the drivers does not commonly occur when the counterbalance is directly up, neither does the maximum rail pressure occur when the counterbalance is directly down. These maximums may take place either before or after the upper and lower points according to the conditions under which the wheel is revolving at the instant." Professor Webb, however, wrote that "if the power supplied is used up by the friction, there is a chance of getting a regular path," and "friction delays the phase, is a rough statement." The authors feel that their Fig. 8, obtained by neglecting friction while still recognizing the effect of friction in producing steady-state vibrations, is very useful in obtaining an over-all viewpoint of the problem considered. This type of general picture of the problem should precede any detailed calculations for a particular case such as the calculations by Professor Webb and Mr. Barnes. The wheel lift for various points on the curves of Fig. 8 increases from zero, where the curve leaves the horizontal axis, to infinity at the point where the various curves intersect. The infinite amplitude at the latter point results because friction has been neglected.

The Thick-Film Lubrication of Full Journal Bearings of Finite Width[1]

EVERETT O. WATERS.[2] The writer has been interested in solving Reynolds' equation for various boundary conditions, and is glad to have an opportunity to compare the methods of others with those which he has found useful in his own work. After reading the paper, he would like to offer the following comments by way of query or interpretation.

1 The various figures in the paper indicate that computations were carried to eccentricity ratios of the order of 0.6. Is the convergence of the successive-approximation method used by the authors sufficiently rapid to make this method feasible for higher eccentricity ratios—say 0.8 or 0.9—and if so, how many approximations would be necessary for reasonably accurate results?

2 The effect of a circumferential groove may be easily shown by considering Reynolds' equation directly. The corresponding homogeneous equation, using the notation of Howarth and Needs, is

$$\frac{\partial}{\partial x}\left(\frac{h^3}{\mu}\frac{\partial p}{\partial x}\right) + \frac{\partial}{\partial z}\left(\frac{h^3}{\mu}\frac{\partial p}{\partial z}\right) = 0$$

and all the solutions of this equation, when superposed upon the solution for infinite width, give the net values of p vs. x and z, provided the boundary conditions are satisfied. Ordinarily, this requires that the solutions of the homogeneous equation be complicated functions of x and z. However, there is one solution, usually trivial, that exactly fits the boundary conditions for a circumferential groove, namely

$$p = c_1 z + c_2$$

This shows at once that the circumferential groove merely adds a component of pressure varying linearly with z to the pressure already fixed by the other conditions.

A further advantage of the circumferential groove, not mentioned by the authors, is the possibility of maintaining a constant carrying capacity for the bearing regardless of the angular position of the load line, which obviously cannot be done when the oil is fed at a point source or a line source parallel to the journal axis.

3 The results presented by the authors for simple 360-deg bearings without circumferential groove or point source are obviously predicated upon the existence of positive absolute pressure throughout the oil film. But since the pressure at the sides of the bearing is the mean of the highest and lowest value, one concludes that the maximum pressure cannot be greater than twice atmospheric, unless oil is fed to the sides of the bearing at more than atmospheric pressure—an unconventional and probably difficult procedure, to say the least. This limits the validity of the results to a fairly narrow pressure range—a limitation which must be strictly observed in making practical use of the authors' numerical and graphical data.

The foregoing remarks are submitted in no spirit of argument or criticism, but rather with the thought of pointing out one or two directions in which the authors will have to carry their research a few steps further before it can be considered as finished. On the contrary, the pioneer work that they have done on the 360-deg bearing is well deserving of high commendation, and doubtless they have already considered the matter of filling in these gaps in order to make the picture complete.

H. REISSNER.[3] The writer having published a paper[4] about the full journal bearing of finite width, would like to remark about the difference in the starting point, the mathematical method used by the authors and himself, and the future research. The authors started from the Reynolds differential equation of lubrication, that is, Equation [1] of the paper under discussion. This equation is a very plausible approximation, neglecting the inertia forces, the curvature of the streamlines, the transverse velocities, and the transverse pressure gradient. It has been applied until now for the treatment of the bearing of infinite width (Sommerfeld) and for the plane bearing of finite width (Michell).

For the journal bearing of finite width Reynolds' equation brings the inconvenience that its coefficients are functions of the circumference angle so that particular solutions of a trigonometrical development are not possible. Therefore, the authors have right from the beginning put up a development in ascending powers of the relative eccentricity of the two bearing cylinders and have split the original equation into a sequence of ordinary two-dimensional potential equations with quasi mass sources each depending on the solution of the preceding equation. In solving these equations they have also been able to take account of a pressure oil feed assuming a radial linear source going from journal to bearing.

The writer's method resembles in one point the work of the

authors in so far as it was the first to use the development in powers of the relative eccentricity for the bearing of finite width as the last step of the analysis.

In other respects it differs fundamentally. Instead of the approximative Reynolds equation it uses the exact differential equation taking into account the curvature of the streamlines, the transverse pressure gradient, and the transverse velocities.

The writer does not want to assert that they are not negligible except perhaps in the vicinity of an oil-fed source where there are transverse velocities decidedly of the same order of magnitude as the tangential velocities and in the case of the partly filled journal bearing.

But the advantage of the exact starting equation

$$\nabla^2(u, v, w) = \text{grad } p$$

lies in the fact that in cylindrical coordinates r, θ, z it has constant coefficients in the directions of θ and z and so can be integrated, fulfilling the corresponding boundary conditions by Fourier series in both directions and in each term. Only in the radial direction Bessel functions arise for which, considering the narrow angular space, very few terms of a series are sufficient.

It is only in order to satisfy the boundary conditions appearing in the form of difference equations that a development of the series coefficients in powers of the eccentricity seemed to be the best way for my method.

The process has been executed so far as to lead to final formulas for the pressure and velocity distribution in circumferential, transverse, and axial direction. The average streamlines (taken over the thickness of the film) going axially outward on the pressure side and inward on the suction side have been calculated and, using as a bearing a glass cylinder, photographically confirmed.

Yet the whole analysis was thought only as a program for future detail and extension work.

Now a few words about some future problems in lubrication which ought to be prepared theoretically.

There is first the question of the partly filled journal bearing which has less friction than the full bearing because the friction on the suction side is avoided. For this case the boundary conditions at the ends of the arc for velocity and pressure had until the writer's papers never been given exactly. As the velocity is not zero at the bounding radii, there must be a free surface running along the nearly empty side of the rotating cylinder. Only in this way can the fundamental difficulties of this question be settled. There will then be obtained a certain relation between embracing arc, load, eccentricity, and feed pressure. It will be difficult for the Reynolds method, neglecting transverse velocities and transverse pressure gradient, to formulate this condition.

We all know further that two important difficult problems are still waiting for a theoretical rational treatment. These concern the change of viscosity by pressure and by temperature. Viscosity changes enormously with pressure and temperature and will be very different in different points of the bearing.[5]

The mathematical difficulties have not been surmounted yet. Still a theory approximative perhaps but giving the essential behavior must be found.

S. Kyropoulos.[6] The investigation constitutes, as an application of the hydrodynamic theory to bearings of the type used in practice, a valuable contribution to the understanding of their working mechanism. The extension of the analysis to bearings fed with lubricant at point sources, and the pertaining experiments with small loads and adequate oil pressures permit an illustrative approximate realization of the limiting conditions visualized by Petroff. The discussions of the bearing with a circumferential groove as a source of oil feed emphasize the nonhydrodynamic factor of better cooling which tends to offset the hydrodynamic disadvantages of such bearings in practice. This explanatory discussion in connection with the theoretical investigations of the paper is particularly fortunate in that it may serve to increase the confidence of the practical designer in the scientific development of the fundamentals of bearing design and operation, the importance of which is not yet sufficiently realized, as practice shows.

With regard to the case of bearings fed with lubricant at point sources in the pressure region, it might not be out of place to sound a warning regarding practical applications. It happened not infrequently that in cases where the oil feed was shifted into the pressure zone the feed pump was unable to pump against the pressure of the oil film and that the bearing even pumped oil into the oil pump.[7]

With regard to the subject of thin film lubrication, mentioned in the introductory remarks of the paper, the writer is inclined to believe that under the conditions of practice, where nonviscous lubrication comes into play, such friction is always connected with wear due to the irregularities of real surfaces. The high local pressures involved result in high local temperatures and chemical high-temperature reactions between lubricated surfaces and lubricants or in the disappearing of the lubricant and local exposure of the "metal" surfaces. Prior to this stage there will occur at the highest spots true friction between adsorption films and, perhaps, such friction will occur also on any adsorption layers on local peaks, exposed by high local temperatures in which case the adsorbed films will scarcely be identical with the original lubricant. Thus the physical investigation of the phenomena will ultimately have to aim at a molecular physical understanding of the law of Amontons-Coulomb.[8]

Authors' Closure

In reply to the question of Professor Waters, concerning the convergence of the approximation method used by the authors, we must admit that, beyond eccentricity ratios of 0.6, the number of approximations which have been used would not suffice to give quantitatively accurate results. Since the method is essentially equivalent to an expression of the pressure distribution as a power series in the eccentricity, its convergence naturally becomes increasingly less satisfactory as the eccentricity increases. For eccentricities close to unity, a different method of approximation would be necessary to obtain significant results.

The detailed treatment of the problem of a circumferential groove is given by the authors in a previous paper.[9] While it is true that the linear-pressure-distribution term, required to give the grooving effect, represents but a trivial solution of the Reynolds equation, the authors were surprised in their failure to find any mention of this solution or of its applicability in the lubrication literature.

The authors fully agree with the warning frequently pointed out regarding the limitation of the use of the Reynolds equation solution in the regions of negative pressure. Therefore, their solutions for the flooded bearing were not intended as ultimate representations of the actual situation which will obtain in flooded bearings. Rather, they were derived and developed

mainly as a necessary preliminary for the study of bearings with lubricant sources such as the circumferential groove or the point source. If the feed pressures in these types of bearings are sufficiently high, the negative pressures will be overcome and the contributions due to the flooded-bearing solutions will possess physical validity.

While it is true that the exact hydrodynamic equation used by Dr. Reissner has constant coefficients in the direction of θ, the difficulty of satisfying exactly the boundary conditions in the radial direction would seem to be about as great as the difficulties of treating the Reynolds equation. Moreover the authors cannot agree that the approximations of the Reynolds equation will be of any consequence in treating practical journal-bearing systems, where the radial clearance is but a small fraction of the over-all dimensions. In fact, as Duffing has pointed out, in the case of the infinitely wide bearing the exact hydrodynamic treatment gives identically the same pressure distribution as found by Sommerfeld when using the Reynolds equation. It is difficult to see how the mere finiteness in width would lead to appreciable errors if the radial clearance is kept small. Even where a source is present the approximations of the Reynolds equation should still remain valid except possibly in the immediate vicinity of the source.

The authors do agree with Dr. Reissner's last remark concerning future problems. The question of negative pressures does indeed still seem to be bothersome, and a study of the boundary conditions from the point of view of the rigorous hydrodynamic equations would be the most promising line of attack.

The difficulty expressed by Professor Kyropoulos of applying the lubricant source in the high-pressure zone of the film is well taken. The theory developed by the authors permits a calculation of the pressure which would be required to maintain any rate of lubricant inflow at the point source. Of course, the rate of inflow will decrease with the applied pressure and, if the external sources cannot maintain a pressure at the inflow point equal to the natural pressure which would be developed there in a flooded bearing, the bearing will even pump lubricant back into the oil pump.

The problem of thin-film lubrication is indeed pressing from a practical point of view. The authors agree with Professor Kyropoulos' interpretation regarding this problem. In fact, it is their belief that the hydrodynamic theory will have to be abandoned completely in this region of lubrication, and that the problem will be solved only by direct experimental investigation.

Chain Links Under Cross Forces[1]

M. V. Barton.[2] In this paper the condition of loading assumed by the author was one in which the forces were exerted by the connecting links at right angles to the supported link. This condition of loading probably would not occur in a chain installation because of the necessity for the connecting links to pass around the supporting chain sheave or drum; also, this condition may not necessarily be the most severe encountered in chain service. For these reasons it may be necessary to consider the stresses in the links adjacent to the one analyzed by the author. The adjacent connecting link would be rotated in position 90 deg with respect to the one analyzed by the author and may be assumed to be supported in its vertical position by the sheave groove or by the restraining action of the connecting links.

For purposes of comparison with the author's results, the circular link as illustrated in Fig. 1 of this discussion will be analyzed. This indeterminate structure may be easily analyzed by means of Castigliano's theorem. The structure with redundants M_0 and H_0 acting is shown in Fig. 2 of this discussion. The moment at any point is

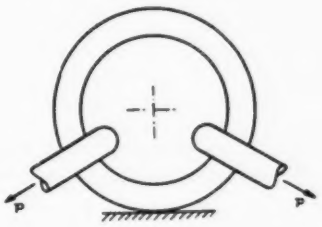

Fig. 1

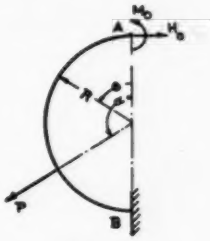

Fig. 2

$$M_1 = M_0 - H_0R(1 - \cos\theta) \quad [1]$$

for $0 \leq \theta \leq \alpha$, and

$$M_2 = M_0 - H_0R(1 - \cos\theta) + PR\sin(\theta - \alpha) \quad [2]$$

for $\alpha \leq \theta \leq \pi$. For continuity, deflection at A in the direction of H_0 equals zero, or

$$\delta_{H_0} = 0 = \frac{\partial V}{\partial H_0} = \int M\frac{\partial M}{\partial H_0}\,d\theta \quad [3]$$

$$= \int_0^{\pi} [M_0 - H_0R(1 - \cos\theta)](1 - \cos\theta)\,d\theta + \int_{\alpha}^{\pi} PR\sin(\theta - \alpha)(1 - \cos\theta)\,d\theta \quad [4]$$

Also change in slope at A equals zero, or

$$\Delta = 0 = \frac{\partial V}{\partial M_0} = \int M\frac{\partial M}{\partial M_0}\,d\theta = \int_0^{\pi} [M_0 - H_0R(1 - \cos\theta)]\,d\theta + \int_{\alpha}^{\pi} PR\sin(\theta - \alpha)\,d\theta \quad [5]$$

Solving these two equations for M_0 and H_0 it is found that

$$M_1 = PR\left[\frac{\pi - \alpha}{\pi}\sin\alpha\cos\theta - \left(\frac{\cos\alpha + 1}{\pi}\right)\right] \quad [6]$$

for $0 \leq \theta \leq \alpha$, and

$$M_2 = PR\left[\frac{\pi - \alpha}{\pi}\sin\alpha\cos\theta - \left(\frac{\cos\alpha + 1}{\pi}\right) + \sin(\theta - \alpha)\right] \quad [7]$$

for $\alpha \leq \theta \leq \pi$.

Investigation shows that for practical angles of the force, the maximum moment occurs where $\theta = \pi$, i.e., at the point of support, then

$$M = \frac{PR}{\pi}[\alpha\sin\alpha - \cos\alpha - 1] \quad [8]$$

and the condition for the maximum value of M is given by

$$2\tan\alpha + \alpha = 0 \quad [9]$$

[1] By Jos. B. Reynolds. Published in the December, 1939, issue of the Journal of Applied Mechanics, Trans. A.S.M.E., vol. 61, 1939, p. A-171.

[2] Instructor in Machine Design, College of Engineering, Cornell University, Ithaca, N. Y.

or for α about equal to 131 deg. For the case $\alpha = 131$ deg

$$M_{max} = 0.44PR \quad \ldots\ldots\ldots\ldots\ldots\ldots [10]$$

This is about 12 per cent less than that found as a maximum by the author. The stress produced however may be higher in this case because the effect of thrust must be added.

Hence

$$\sigma = \frac{Mc}{I} + \frac{H}{A} \quad \ldots\ldots\ldots\ldots\ldots\ldots [11]$$

where $H = P \sin \alpha - H_0 = 0.552P$. This stress will of course be increased by the shift of the neutral axis which has not been considered here.

It is evident therefore that it is possible to obtain stresses which are higher than those determined by the author at practical angles of application of the forces.

It might also be pointed out that the deflections found from geometrical considerations by the author may be very easily verified by the use of Castigliano's theorem, that is

$$\delta = \frac{\partial V}{\partial P} = \int_0^{\frac{\pi}{2}} \left[\frac{M_n}{EI_n} \frac{\partial M_n}{\partial P} + \frac{M_t}{GI_t} \frac{\partial M_t}{\partial P} + \frac{KQ}{A_c G} \frac{\partial Q}{\partial P} \right] Rd\theta \quad \ldots\ldots [12]$$

$$= PR^3 \left[\frac{1}{2EI_n} (\pi - 2) + \frac{1}{GI_t} (\pi - 3) \right] + \frac{KPR}{A_c G} \frac{\pi}{2} \quad \ldots\ldots [13]$$

where K is a shear deflection factor having a value of about unity for circular sections and 6/5 for square sections.

Author's Closure

The theory of the paper deals only with the conditions under which tests for verification were run. Many other circumstances are not only possible but in accord with actual conditions. In general, when the link lies flat on the sheave, the forces applied at the ends of the link will not be perpendicular to the plane of the neutral axis of the link, but will have components tending to stretch the link as well as components tending to bend it.

Mr. Barton has made a significant contribution to the general theory. An analogous method might be employed to analyze the case of an oblong link under corresponding circumstances. It can hardly be assumed in these cases, however, that P has the same value as in the case discussed in the paper.

Analysis of Spherical Shells of Variable Wall Thickness[1]

Stefan Bergmann.[2] The author has published a contribution to the theory of elasticity of the spherical shell for the case where certain terms in the differential equations can be neglected, provided the thickness of the shell varies according to the law[3]

$$\delta = d(1 + \alpha\varphi)^2$$

Since the author's (approximate) solution appears in a form very convenient for numerical calculations, his result is to be considered as a valuable contribution to the theory of thin shells.

Nevertheless, it appears to be of practical importance to insert a few remarks on the exact theory of spherical shells as affected by external forces and of the wall thickness which varies according to another law. In this connection the attention of the reader should be called to a method for the solution of related problems, indicated by the writer and used and worked out in detail by Berentzen.[4]

The latter considers the problem of a spherical ring shell the thickness of which varies according to $\delta = 0.16a\varphi/t$, the external forces being represented by its own weight and by hydrostatic pressure; t is a parameter upon which the thickness of the ring shell depends.

The publication[4] was intended mainly as a contribution to the theory of dams. Introducing spherical coordinates a, φ, θ, the neutral surfaces of such a "shell" dam are given by $\varphi_0 \leqq \varphi \leqq \varphi_u$, $\theta_0 \leqq \theta \leqq \theta_u$. Berentzen considers a shell $\varphi_0 \leqq \varphi \leqq \varphi_u$, $0 \leqq \theta \leqq 2\pi$, as shown in Fig. 1 of this discussion. The method employed in his paper aims to give—with the aid of certain functions

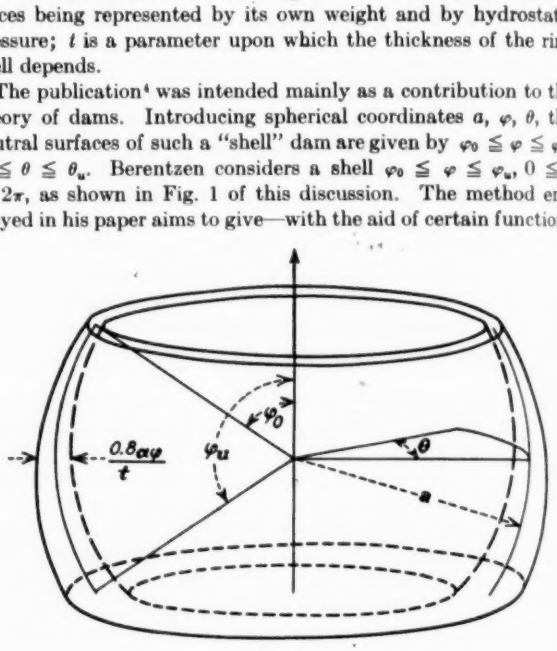

Fig. 1

tabulated once for all—a comparatively concise solution for every value of t, for arbitrary height of the water surface, for arbitrary φ_0 and φ_u, and for arbitrary boundary conditions.

As auxiliary quantities are introduced X and the quantity $M = t^3 \frac{3 \times 10^3 Q}{a^2 E}$ instead of Q. Starting then from Reissner's equations, he obtains (instead of Spotts' Equations [46] and [54]) the following equations

$$\left(\frac{\pi}{2} + \beta\right)^3 X''' + \left(\frac{\pi}{2} + \beta\right)^2 \left(-tg\,\beta + \frac{6}{\pi + 2\beta}\right) X'' + \left(\frac{\pi}{2} + \beta\right)^2 \left(-tg^2\beta - \mu + \frac{6\mu\, tg\,\beta}{\pi + 2\beta}\right) X = -\frac{5(1-\mu^2)}{216} M$$

$$\left(\frac{\pi}{2} + \beta\right) M'' + \left(\frac{\pi}{2} + \beta\right) \left(-tg\,\beta - \frac{2}{\pi + 2\beta}\right) M' + \left(\frac{\pi}{2} + \beta\right)^2 \left(-tg^2\beta + \mu - \frac{2\mu\, tg\,\beta}{\pi + 2\beta}\right) M = \frac{3}{4} 10^3 \left(\frac{\pi}{2} + \beta\right)^2 t^2 X + \frac{3.10E}{8a^2E} t^4 \phi^*(\beta)$$

where $\beta = \varphi - \frac{\pi}{2}$, $\phi^*(\beta) = \phi\left(\beta + \frac{\pi}{2}\right)$, $X(\beta) = \chi(\beta + \pi/2)$

The quantity $\phi^*(\beta)$ depends linearly on parameters α_ν, $\nu = 1, 2, 3, 4$, the values of which depend on the height of the water

[1] By M. F. Spotts. Published in the September, 1939, issue of the Journal of Applied Mechanics, Trans. A.S.M.E., vol. 61, 1939, p. A-97.

[3] Throughout this discussion, the writer uses the nomenclature adopted by the author.

[4] "Untersuchungen über Spannungen einer unter äusseren Wasserdruck und Eigengewicht stehenden Kugelringschale mit veränderlichen Dicke," by W. Berentzen. Edited Köln, 1936.

surface, the angles φ_0 and φ_u, the specific weight of the material of the shell, the constant t, and Poisson's ratio μ.

The general solution of the system of equations of this discussion appears in the form

$$X(\beta) = \sum_{\nu=1}^{8} \alpha_\nu X_\nu(\beta), \qquad M(\beta) = \sum_{\nu=1}^{8} \alpha_\nu M_\nu(\beta)$$

wherein the $X_\nu(\beta)$ and $M_\nu(\beta)$ are properly chosen particular solutions depending only on t and μ, but independent of all other parameters aforementioned. By choosing in an appropriate manner α_ν we get the sought solution of the considered problem.

It remains to determine the $X_\nu(\beta)$, $M_\nu(\beta)$, $\nu = 1, 2, \ldots 8$ as functions of t and μ. It may be assumed that the variations of μ are small ($\mu_0 - \epsilon \leqq \mu \leqq \mu_0 + \epsilon$, $\epsilon \ll 1$). For $X_\nu(\beta)$ and $M_\nu(\beta)$ certain power series

$$X_\nu(\beta) = \sum_{\vartheta=0}^{\infty} A_{\nu\vartheta}{}^{(1)} \beta^\vartheta, \qquad M_\nu(\beta) = \sum_{\vartheta=0}^{\infty} A_{\nu\vartheta}{}^{(2)} \beta^\vartheta$$

are obtainable whose coefficients $A_{\nu\vartheta}{}^{\delta}$ depend on t and μ. These power series converge for every β in the interval -90 deg $< \beta < 90$ deg. Therefore, if they are considered in a partial interval, e.g., -30 deg $< \beta < 30$ deg, there is rapid convergence and if eight terms are taken the error committed is much less than 1 per cent. The coefficients $A_{\nu\vartheta}{}^{\delta}$ in the power series are polynomials (and not power series of t as it would be in the case of a more general system of equations) in t^2 and μ the degree of which is increasing gradually with ϑ. The coefficients $A_{\nu\vartheta}{}^{\delta}$, $\vartheta \leqq 8$ are not higher than of the second degree in t^2 and, as $\mu - \mu_0$ is very small, we shall have

$$X_\nu = (X_{\nu_1} + X_{\nu_2}t^2 + X_{\nu_3}t^4) + (\mu - \mu_0)(X_{\nu_4} + X_{\nu_5}t^2 + X_{\nu_6}t^4)$$

$$M_\nu = (M_{\nu_1} + M_{\nu_2}t^2 + M_{\nu_3}t^4) + (\mu - \mu_0)(M_{\nu_4} + M_{\nu_5}t^2 + M_{\nu_6}t^4)$$

It is advantageous to tabulate not only $X_{\nu\delta}(\beta)$ and $M_{\nu\delta}(\beta)$ but also $X_{\nu\delta}'(\beta)$, $M_{\nu\delta}'(\beta)$, as well as two other certain quantities occurring in the computations.

Not all of these quantities have been calculated by Berentzen yet. But he establishes all of the equations which are necessary to calculate the series. He calculates furthermore all of the functions $X_\nu(\beta)$, $M_\nu(\beta)$, $X_\nu'(\beta)$, $M_\nu'(\beta)$ mentioned for definite values of t and μ and shows in detail how the constants α_ν are to be determined from the given water height, from the weight, and from the boundary conditions.

M. Hetényi.[5] When a thin shell of revolution is subjected to axially symmetrical edge loading the stresses are of a damped-wave character, rapidly decreasing along the meridian away from the loaded hoop circle. The thinner the shell and the larger the angle of opening, the more concentrated are the stresses in the edge region. For such cases it is satisfactory to use the solution by Geckeler, who takes into account only the highest derivatives in the differential equations of the problem and thereby substitutes the edge region of a shell of revolution by a cylindrical shell. If the shell is somewhat thicker $\left(\frac{a}{\delta} < 40\right)$ or its angle of opening is small ($\varphi < 45$ deg), then Geckeler's solution will involve considerable error and a better approximation is needed, which would take into account also the derivatives next to the highest in the differential equations. The author has accomplished this by a suitable change in the variable and his approximation is of the same order as the one investigated by Blumenthal[6] and by the writer[7] for spherical shells of constant wall thickness.

This type of solution is termed asymptotic and has a point of singularity at the vertex of the shell where it gives infinite values for the unknown quantities. As a rule this singularity affects only the immediate neighborhood of the vertex; however, in Fig. 4 of the paper, even at 5 deg away from the vertex, the angular deflection χ shows no tendency of approaching zero, which value it should assume at the top. It would be interesting to know whether that divergence is due to the singularity at the vertex or to some other reason.

The accuracy of the author's solution is probably high, though it would be of interest to try to estimate the involved percentage error in the same manner as has been done by the writer for shells of constant thickness. The variable wall thickness assumed in the paper is apt to follow the actual stress distribution in shell constructions and the author is to be congratulated for this valuable contribution to the theory of thin shells.

The Spring Clutch[1]

A. M. Wahl.[2] The author has presented an interesting analysis of a device which should probably find in the future a wider application than it has had in the past. For example, a possible additional use might be in torque-limiting mechanisms, since, as the author shows, by using a relatively few turns the unwinding torque may be kept practically constant irrespective of the actual magnitude of the coefficient of friction. Such torque-limiting devices could be made to operate in both directions by using two springs, wound in opposite directions, in series on coaxial arbors.

The author derives the expression for limiting torque T by assuming initially a constant force f_0 per unit length produced by assembly of the spring. This force f_0 is determined from energy considerations. The differential relations of an element of the wire are set up and by integration the torque is determined. Near the end of the spring there will be a tendency of the spring to lift from the arbor as indicated in Fig. 1*b* of this discussion, while a concentrated load P' also acts at this end.

It will be of interest to apply curved-bar theory to this problem and to compare the results with those obtained by the author. If r is the mean radius of curvature of the circular ring and u the radial deflection (taken positive toward the center of the ring) at any point at an angle ϕ, as shown in Fig. 1*b*, it may be shown that the following differential equation holds.

$$\frac{d^2u}{d\phi^2} + u = -\frac{Mr^2}{EI} \qquad [1]$$

where M is the bending moment at the angle ϕ.[3]

The equations of equilibrium of an element of the bar may be obtained from Fig. 1*a* (by neglecting small quantities of higher order). These are (for the unwinding condition where the friction force $\mu prd\phi$ is in the direction shown)

$$\frac{dM}{d\phi} = Qr - \frac{\mu prh}{2} \qquad [2]$$

$$\frac{dQ}{d\phi} = pr - P \quad \ldots\ldots [3]$$

$$\frac{dP}{d\phi} = Q - \mu pr \quad \ldots\ldots [4]$$

where Q = shearing force, lb; μ = coefficient of friction; p = radial pressure in pounds per inch acting at angle ϕ; r = mean radius of spring; and h = depth of cross section, in.

(a)

(b)

FIG. 1 SPRING CLUTCH

Where the spring is in continuous contact with the arbor, and the outward radial deflection is δ, where δ is the difference between the arbor radius and initial spring radius, we have from Equation [1] (since $d^2u/d\phi^2 = 0$ for u = const)

$$\delta = \frac{M_0 r^2}{EI} \quad \ldots\ldots [5]$$

where M_0 is the constant moment.

Also where the spring is in continuous contact with the arbor, from Equation [2]

$$\frac{dM}{d\phi} = 0 = Qr - \frac{\mu prh}{2} \quad \ldots\ldots [6]$$

or

$$Q = \mu ph/2 \quad \ldots\ldots [7]$$

From Equation [4], using Equation [7]

$$\frac{dP}{d\phi} = Q - \mu pr = -\mu pr\left(1 - \frac{h}{2r}\right) \quad \ldots\ldots [8]$$

Since in most practical clutch springs h is small compared to r

$$\frac{dP}{d\phi} \approx -\mu pr \quad \ldots\ldots [9]$$

By differentiating Equation [1] and using Equations [2], [3], and [9] we have

$$\frac{dp}{d\phi} + \mu p - \frac{\mu h}{2r}\frac{d^2p}{d\phi^2} = 0 \quad \ldots\ldots [10]$$

The solution of this equation is (for small h/r)

$$p = Ae^{2r\phi/\mu h} + Be^{-\mu\phi} \quad \ldots\ldots [11]$$

For the unwinding condition, it may be expected that $A = 0$, since p cannot continue to increase with increasing ϕ; hence

$$p = Be^{-\mu\phi} \quad \ldots\ldots [12]$$

The angle ψ from the end of the spring at which contact is established with the arbor may be determined as follows:

At $\phi = 0$, the moment, shearing force, and direct load are respectively

$$M_0 = P'r\,[\sin\psi + \mu(1 - \cos\psi)] \quad \ldots\ldots [13]$$

$$Q_0 = P'(\cos\psi + \mu\sin\psi) + X_0 \quad \ldots\ldots [14]$$

$$P_0 = P'(\sin\psi - \mu\cos\psi) - \mu X_0 \quad \ldots\ldots [15]$$

These equations are obtained from conditions of static equilibrium, the force X_0 being an assumed concentrated load acting radially outward at $\phi = 0$; it is not shown in Fig. 1 of this discussion. This force is necessary to satisfy conditions near the end of the spring. In addition, since the end of the spring must deflect outward by an amount $\delta(1 - \cos\psi)$ relative to point 0, shown in Fig. 1 of this discussion (due to forces P' and $\mu P'$), we have from curved-bar theory

$$\delta = \frac{P'r^3}{EI}\left\{\frac{\psi}{2} - \frac{\sin\psi\cos\psi}{2} + \mu(1 - \cos\psi) - \frac{\mu\sin^2\psi}{2}\right\}\left\{\frac{1}{1 - \cos\psi}\right\} \quad \ldots\ldots [16]$$

Also from Equations [2], [3], and [7] for small h/r

$$\left.\begin{aligned} P_0 &= p_0 r = Br \\ Q_0 &= \frac{\mu p_0 h}{2} \end{aligned}\right\} \quad \ldots\ldots [17]$$

where p_0 is the unit radial load at $\phi = 0$.

From Equations [5], [13], and [16], we find if μ is not too large that an approximate expression in radians for ψ is

$$\psi = 2.14 + 1.42\mu \quad \ldots\ldots [18]$$

These equations enable us to determine p_0 by using approximate expressions for $\sin\psi$ and $\cos\psi$. Thus

$$p = \frac{\delta EI}{r^4}\frac{(1 - 0.92\mu)}{(1 + 0.92\mu)}e^{-\mu\phi} \quad \ldots\ldots [19]$$

The free torque is given by

$$T = \int_0^{2\pi N'} \mu p r^2 d\phi + \mu(P' + X_0)r$$

where N' = number of turns in contact with arbor measured from point $\phi = 0$ (note that this is not the total number of turns). Using the values of P' and X_0 found from the foregoing equations, the expression for free torque becomes

$$T = \frac{\delta EI}{r^2}\left[\frac{(1 - \epsilon^{-2\pi N'\mu})\ (1 - 0.92\mu) + 1.84\mu}{(1 + 0.92\mu)}\right] \quad [20]$$

For $N'\mu$ greater than about 1, the exponential term may be neglected and the equation reduces to

$$T = \frac{\delta EI}{r^2} \quad [21]$$

This value of torque coincides with the value given by Equation [5] of the paper[1] if h/r is small and the value of f_0 given by Equation [19] of the paper is used.

For the slipping torque it is merely necessary to change the sign of μ in the preceding equations. In this case the first term on the right side of Equation [11] may be neglected as far as any contribution to the torque is concerned since r/h is assumed very large and with μ negative the exponential term dies out very rapidly. Hence Equation [20] may still be used if the sign of μ is changed.

This gives for the slipping torque

$$T' = -\frac{\delta EI}{r^2}\left[\frac{(\epsilon^{2\pi N'\mu} - 1)\ (1 + 0.92\mu) - 1.84\mu}{1 - 0.92\mu}\right] \quad [22]$$

where the negative sign signifies a torque in an opposite direction to the free torque.

It should be noted that Equation [22] of this discussion differs somewhat from Equation [8] of the paper, the difference being accounted for by the assumptions made as to conditions near the end of the spring. Also the value N' for number of turns in contact with the arbor is used rather than total turns N as used by the author. Since the angle ψ at which contact is established, shown in Fig. 1, is approximately $(2.14 - 1.4\mu)$ radians for the slipping condition (obtained by changing the sign of μ in Equation [18]) it may be expected that N' will be around $^1/_4$ to $^1/_2$ turn less than N. For the larger values of N, if this difference between N and N' is taken into account, the results calculated from Equation [22] of this discussion will not differ much from those calculated from Equation [8] of the paper. In actual springs, however, considerable deviation from the ideal conditions assumed in the analysis may be expected in many cases and this may result in considerable difference between calculated and test values of the slipping torque. Such deviations may also account for the ± 20 per cent variations in slipping torque found experimentally by the author.

It is interesting to note that if we assume a zero coefficient of friction, then from Equation [19] of this discussion the radial pressure becomes constant and equal to

$$\frac{\delta EI}{r^4}$$

For small values of h/r this equation coincides with the expression for f_0 obtained by the author from Equation [19] of the paper for the radial load on the spring when no torque is applied. This expression for f_0 thus involves the assumption that frictional effects are negligible during assembly of the spring on the arbor.

Author's Closure

The curved-beam theory has the advantage of yielding an expression for the end effect, that is, for the portion of the turn which does not contact the arbor. From Equations [18] and [16] of the discussion, it is possible to calculate the inward force P' at the end of the spring. One can then decide whether or not it is necessary to grind or otherwise treat the end of the spring in order to reduce the bearing pressure to a safe value. On small spring clutches no special end treatment is generally required but on larger sizes, intended to give high values of free torque, end treatment is necessary to prevent excessive wear.

The curved-beam theory has the disadvantage of resulting in a more complex derivation and a more complex expression for the torque and in addition it requires, on the part of the reader, a more detailed knowledge of elastic theory than does the energy method. Both methods introduce an approximation regarding the smallness of the ratio of h/R_1 but it is not obvious which derivation results in the better solution in cases where h/R_1 is not very small.

The most sensitive test of the equations are data such as are shown by the torque curve of Fig. 4 of the author's paper. For the case shown in Fig. 4, Equation [21] of the discussion would give about 3.5 per cent lower value of torque at the 0.193-in. arbor diameter and a 3 per cent higher value at the 0.182-in. arbor diameter. It is believed that the data would have shown up such differences. This cannot be taken as conclusive evidence for choosing between the two equations and more data would be required to settle the point. The percentage difference between the two equations is given by $100\ (\delta - h/2)/R_1$ and hence for values of h/R_1 of about 0.2 one might expect a 10 per cent difference between the two methods of calculation. This difference is large enough to permit easy experimental differentiation between the two relations.

The Forces Required for Rolling Steel Strip Under Tension[1]

C. W. MacGregor.[2] Dr. Nádai is to be congratulated upon this noteworthy contribution to our knowledge of the stresses set up during the rolling of steel. The extension of the solution to the cases of front and back tension is very interesting and will prove of considerable value in that it clearly brings out the effects of certain variables, such as friction on the shape of the pressure distribution between the rolls and the bar.

It appears that during rolling under well-lubricated conditions the assumption that p is a principal stress represents the true case very closely. When dry friction is assumed, or if metal to metal contact is present, p will then probably differ somewhat from the principal stress at the point of contact. The writer would therefore like to ask Dr. Nádai if any calculations have been made in order to show the magnitude of this effect.

Recently cold rolling tests were made at the Massachusetts Institute of Technology during which motion pictures were made of the flow layers obtained on the highly polished surface of the rolled bar as it passes between the rolls in the rolling mill.[3] The bars were of Bessemer screw stock, 1 in. square in cross section, and the rolls about 6 in. in diameter. The reductions used were from 1 to $2^1/_2$ per cent. A special apparatus using reflected light was designed in order to photograph the flow layers in motion.

It was found that the flow layers received were simple cycloids checking very closely those predicted by Prandtl's solution for plastic flow between two rough parallel plates.

---

[3] "The Plastic Flow of Metals," presented at the A.I.M.E. Meeting during the National Metals Congress in Detroit, Oct. 17, 1938.

Since the rolling problem is indeed very complicated with such a large number of variables entering the problem, the method adopted by Dr. Nádai of inquiring into the effect of changing one variable at a time appears to be perhaps the best procedure to give us the fundamental information so needed to clarify this problem. It is hoped that he will continue the work along these lines.

Author's Closure

The surface friction between rolls and the piece to be rolled mentioned by Dr. MacGregor deeply influences the structure of the rolled piece and the distribution of the stresses in the contact areas. Conditions in this respect may be widely different in the case of hot rolling or when a strip is cold-rolled and at the same time one of the high-pressure lubricants is applied. Axial tension must also have a deep effect on the stress distribution and probably makes it more uniform along a line which is perpendicular to the plane of the sheet. It is known that a few cases have been treated, in which the nonuniform stress distributions were determined in a layer of a plastic material squeezed out under pressure between rigid plates. The case of parallel plates and that of two slightly inclined plates have been treated. It appears, therefore, that it may be possible perhaps to improve the assumptions which were made in the paper for describing the states of stress in the compressed portion of a sheet, so that account also of the tangential forces is taken retarding the flow of the plastic material when it is compressed between the rolls. The experiments by Dr. MacGregor may throw additional light on the influence of the surface friction and should be of assistance in the future, when such improved computations should be carried out.

Mathematical-Machine Determination of the Vibration of Accelerated Unbalanced Rotor[1]

F. M. Lewis.[2] A solution of the problem of the vibration of an accelerated unbalanced rotor can be obtained by the same procedure, using complex functions, which was utilized in the writer's paper[3] "Vibration During Acceleration Through a Critical Speed," which was referred to by the author.[1]

If the eccentricity of the mass M is e then the magnitude of the exciting force becomes

$$M \frac{\omega^2}{\omega_n^2} e\omega_n^2 = \frac{r^2}{q^2} ek \quad \ldots\ldots [1]$$

and if the resonance factor R is now equal to x/e, then the dimensionless solution corresponding to Equation [15] of the 1932 paper[3] becomes

$$R = -\frac{i\pi e^{i\sigma}}{q^2\delta} e^{2\pi i u_3 r}\left[\int_0^r r^2 e^{i\pi[(r^2/q)-2ru_1]}\,dr - e^{2\pi i u_3 r}\int_0^r r^2 e^{i\pi[(r^2/q)-2ru_3]}\,dr\right] \quad \ldots\ldots [2]$$

Here R is the same quantity as the x/e or u of Baker's paper,[1] but the other symbols are identical with those of the 1932 paper.[3]

We will indicate the method of solution without carrying out all the work in detail.

With the complex substitution

$$r = \sqrt{\frac{iz_1 q}{\pi}} + qu_1 \quad \ldots\ldots [3]$$

the equation obtained from Equation [2] of this discussion contains three integrals

$$\int_0^r e^{-z_1}\,dz_1 \quad \ldots\ldots [4]$$

$$\int_0^r \frac{1}{\sqrt{z_1}} e^{-z_1}\,dz_1 \quad \ldots\ldots [5]$$

$$\int_0^r \sqrt{z_1}\, e^{-z_1}\,dz_1 \quad \ldots\ldots [6]$$

The solution of Equation [4] is obvious, while Equation [5] appears in the solution for an exciting force of constant amplitude.

Integrating by parts, Equation [6] of this discussion can be written

$$\int_{z_1}^{\infty r} \sqrt{z}\, e^{-z}\,dz = \sqrt{\pi}\,K + \sqrt{z_1}\, e^{-z_1} + \frac{1}{2}\int_{z_1}^{\infty r} \frac{1}{\sqrt{z}} e^{-z}\,dz \quad \ldots\ldots [7]$$

After these substitutions and reduction there is obtained the solution

$$R = -\frac{1+i}{\sqrt{2}} + \frac{\sqrt{\pi q}}{2\delta}\left[\frac{i}{2\pi q}\left\{\varphi_1 - \varphi_2 + 2\sqrt{\pi}\, e^{z_1} K\right\} + u_1^2(\varphi_1 + 2\sqrt{\pi}\, e^{z_1} K) - u_2^2\varphi_2\right] \quad \ldots\ldots [8]$$

The φ_1 and φ_2 integrals were evaluated for the 1932 paper[3] so that results for the present case can be easily obtained, the only additional operations needed being multiplication and division, provided that the same $r^2\pi q$ values are used for which φ_1 and φ_2 were previously computed.

The writer has evaluated the solution for $q = 40.8$, $\gamma = 0.051$ accelerated motion, which is very close to Baker's curve for $q = 40.8$, $\gamma = 0.050$ and by interpolating between Baker's curves for $\gamma = 0.05$ and $\gamma = 0.1$ a close check can be obtained in this case.

A comparison between points on the curve $q = 40.8$, $\gamma = 0.051$ by the machine and complex integral calculation is given in Table 1 of this discussion.

TABLE 1

β	u_3 or R — Machine	u_3 or R — Lewis' Equation [8]
0.924	4.0	3.98
1.000	7.6	7.58
1.076	12.6	12.42
1.107	13.7	13.45
	Peak	
1.122	13.7	13.30
1.150	11.5	11.34
1.198	3.7	3.68

The curves are almost identical in shape, having their maximum at the same β value. The peak value of the differential-analyzer curve appears to be high by $2^1/_2$ or 3 per cent.

The peak value of the deceleration curve was computed and the machine curve appears to be high by $3^1/_2$ per cent.

In view of the difficult problem given the machine, virtually amounting to summing a considerable number of positive and

[1] By J. G. Baker. Published in the December, 1939, issue of the Journal of Applied Mechanics, Trans. A.S.M.E., vol. 61, 1939, p. A-145.

negative loops, such an agreement can be considered remarkably close. It is to be expected that for lower q values and higher γ values a still closer check could be obtained.

Author's Closure

In the oral discussion attention was called to a paper, "The Transient Vibrations of Machines," by W. E. Johnson, published in the *General Electric Review*. The author was not aware of this paper, which should have been included in the references noted. The present paper differs mainly by including the effect of damping.

Professor Lewis' discussion is especially valuable in that it not only demonstrates an entirely mathematical method of obtaining the results of the paper, but also substantiates the accuracy of the mathematical machine used. The author is grateful for Professor Lewis' contribution.

Book Reviews

The Timoshenko Commemorative Volume

THE MECHANICS OF SOLIDS. A Collective Work. The Macmillan Company, New York, N. Y., 1938. Cloth, 6 × 9 in., 277 pp., illustrated, $5.

REVIEWED BY S. C. HOLLISTER[1]

ON the evening of December 6, 1938, at the time of the Annual Meeting of The American Society of Mechanical Engineers in New York, a notable group met at dinner to do honor to Professor Stephen Timoshenko. On that occasion his many friends presented him with a volume of collected writings to mark his approaching sixtieth birthday. This volume is made up of papers contributed by twenty nine of his friends, associates, and former students, each writing in his special field of interest. It is the first commemorative volume of the kind to appear in this country.

It is only natural, and indeed very fitting, that the group of authors reflect Professor Timoshenko's relation to the International Congresses for Applied Mechanics; his years at Westinghouse; his many friendships and associations in the Applied Mechanics Division of this Society, of which he was a leading sponsor; and his decade of teaching at the University of Michigan. It characterizes the quality of his leadership, both as an authority in the field of mechanics to which he has devoted his life, and as an organizer in strengthening the research and teaching in that field.

During the century or more that engineering training has been given in America, applied mechanics has rested chiefly on the older tradition of the English-speaking countries abroad. In the early part of the nineteenth century, the prevalent works here were those of Navier and Poisson. By the middle of the century the English translation of Weisbach was available, and about that time an American edition of Moseley, and the work of the great Scottish engineer Rankine, came into common use. The latter work especially had a profound influence on the scope and methods of instruction in mechanics in this country. The French tradition had disappeared, and the Russian tradition, founded by Euler, was almost unknown. Such a development was inevitable, chiefly owing to the remoteness of frontiers where other languages were spoken, and the consequent scanty knowledge among engineering students of other tongues than English.

Late in the century American works on mechanics began to appear. The books by Merriman and Church came into general use. They carried on the same tradition as before, with only fragments drawn from French and German schools.

The first two decades of the present century witnessed an attempt to "simplify" the writings of earlier authors. Mechanics in this period did not move forward here as it did abroad. The disparity between the status of the subject here and abroad became increasingly marked. It was into such a situation that Timoshenko came at the end of the World War.

We have witnessed during the last two decades a tremendous stimulation in the study of mechanics in this country. In this development Timoshenko has played a leading part. The books "Applied Elasticity" (1923) by Timoshenko and Lessells, and "Strength of Materials" (1930) by Timoshenko, have exerted a profound influence upon the teaching of mechanics in America. The organization of the A.S.M.E. Applied Mechanics Division and the initiation of that Division's publication, JOURNAL OF APPLIED MECHANICS, to both of which Timoshenko gave impetus, have further strengthened the field by furnishing a forum for the discussion of practical problems in dynamics, elasticity, and plasticity.

It is no wonder, then, that a spontaneous desire arose to do honor to Timoshenko on his sixtieth birthday anniversary. He has personally left a profound impression upon the advancement of mechanics in this country, both on its teaching and upon its practical application to problems in industry. As a teacher he has that rare gift of developing men to a new level of competence, as contrasted with the frequent practice of merely presenting courses.

Handsome as the present volume is as a tribute to the genius of Timoshenko, it is a notable book in its own right. The authors include distinguished European writers as well as many well-known American teachers and engineers. The contributions deal with the whole gamut of mechanics of solids, both in fundamental aspects and in practical applications. As a reference work it will be sought after by many workers in dynamics, elasticity, elastic buckling, plasticity, and soil mechanics.

Bending of Plates

MOMENTENTAFELN UND EINFLUSSFLÄCHEN FÜR KREUZWEISE BEWEHRTE EISENBETONPLATTEN. By Ernst Bittner. Julius Springer, Vienna, 1938. Paper, 7 × 10 in., 86 pp., 16 figs., and 81 tables, 9.60 rm.

REVIEWED BY S. TIMOSHENKO[2]

THE problem of bending of a simply supported rectangular plate by a uniformly distributed load is completely solved not only in the case when the load is distributed over the entire surface of the plate but also in the case when the load is distributed over a rectangular area representing only a portion of the surface of the plate. In the design of plates used as a floor of a highway bridge we have a more complicated problem of bending of plates under the action of concentrated loads. The practical

[2] Professor of Theoretical and Applied Mechanics, Stanford University, Stanford University, California. Fellow A.S.M.E.

solution of this problem is discussed in the Bittner book. To find, in each particular case, the most unfavorable loading condition, influence surfaces are introduced. By using these the maximum bending moment for any combination of loads can be readily obtained. The concentrated forces in this calculation are replaced by loads distributed over small rectangular areas.

The first part of the book contains the general explanation of the use of influence surfaces and gives a numerical example in which the method is illustrated with all necessary detail. The second part of the book contains numerical tables of influence numbers calculated for various ratios of the sides of the plate and for various magnitudes of the loaded rectangle. The third part of the book is of a more theoretical character. It includes the discussion of the general theory of rectangular plates which was used in the calculation of the influence numbers and also a discussion of some approximate solutions which were used in the case of plates with built-in edges.

The book is of considerable importance for engineers who are designing concrete slabs submitted to the action of systems of traveling loads as for case of highway bridges. Most of the numerical tables appear for the first time and will be useful to designers.

Theoretical Mechanics

THEORETICAL MECHANICS. By Carl Jenness Coe, Ph.D., Assistant Professor of Mathematics, The University of Michigan. The Macmillan Company, New York, N. Y., 1938. Cloth $5^1/_2 \times 8^1/_2$ in., xii and 555 pp., 102 figs., $5.

REVIEWED BY J. N. GOODIER[3]

THIS book covers courses given by the author in the department of mathematics, University of Michigan, one introductory and one advanced, throughout the year. A year's work in calculus is suggested as adequate mathematical preparation.

The preface discusses the present position of Newtonian mechanics in relation to relativity mechanics. A very readable introduction justifies the study of the former on the grounds that the extent to which it explains the physical world is much more surprising than the fact that there are cases in which it does not. The point of view throughout the book is correspondingly philosophical, with virtually no regard to practical application. Such regard is of course not pertinent in a "Theoretical Mechanics," except incidentally where the author chooses to illustrate principles by means of actual mechanisms. Then the student may be led to believe that a physical problem has been solved, when, in fact, tacit idealization has destroyed its reality.

The analytical treatment begins with a concise discussion of the rectilinear motion of a particle. The next chapter is an introduction to vectors; vector analysis is then employed consistently throughout the book. The chapter on curvilinear motion proceeds at once to space curves with subsequent specialization to plane curves. The special topics include finite pendulum motion and planetary motion. Rigid-body mechanics begins with the general kinematical theorems for the fixed point and the fixed axis, and includes "twists" or "screws" as general motions. Then comes a chapter on sliding vectors—vectors localized in a line, as forces in statics. This covers the reduction of vector systems, or the composition of forces in the older specialized language. In the chapter on statics of particles and of a rigid body, simple frames and centroids are included; the following chapter deals with the flexible cord and funicular polygon.

The discussion of virtual work is preceded by a section on constraints, where it is emphasized as a principle that motions of a set of particles satisfying the imposed conditions are as a whole neither aided nor opposed by the constraints. It has proved difficult to realize any clear meaning in this as it stands, in spite of physical illustrations provided. It is only later that the author's intentions become apparent, when he lays down postulates as to the work of the constraints, whereupon the "principle" in question seems to become redundant.

The chapter on kinetics of particles introduces the momentum and energy theorems, and, in brief, the problem of n bodies. The treatment of moments of inertia in the chapter on kinetics of a rigid body is in terms of vector analysis, but is very much more cumbersome than the usual coordinate treatment. The mechanical subjects of the chapter are free motion in a plane, motion about a fixed point, including tops, and about a fixed axis. There is then a chapter on general principles of mechanics. Throughout the book are admirable short historical sections.

A final chapter on potential theory is preceded by a treatment of scalar and vector fields, with the theorems of Green and Stokes. The potential theory, as may be expected, is put on a rigorous basis. There is an excellent set of problems, including potentials of ellipsoids of revolution for axial points.

The book contains in all 696 problems for the student.

Elements of the Topology of Plane Sets of Points

ELEMENTS OF THE TOPOLOGY OF PLANE SETS OF POINTS. By M. H. A. Newman. The University Press, Cambridge; The Macmillan Company, New York, N. Y., 1939. Cloth $5^1/_2 \times 8^3/_4$ in., viii and 222 pp., 93 figs., $3.50.

REVIEWED BY W. L. AYRES[4]

ROUGHLY topology may be defined as "rubber sheet geometry." While this is not accurate it gives a rather clear conception of the nature of the subject. Each branch of geometry is the study of those properties invariant under a particular transformation. For example, Euclidean geometry is the study of properties which remain unchanged under rigid motions. In topology the transformation in question is any single-valued continuous one which has a single-valued continuous inverse. Such a transformation is called a homeomorphism and topology is the study of those properties of spaces which are unchanged by homeomorphisms. For example, a circle cuts its plane into two regions and one of the oldest and most famous theorems of topology, the Jordan curve theorem, states that every homeomorphic transform of a circle cuts its plane into exactly two regions.

While topology is of prime importance in the various branches of mathematics, for the present it finds little application in any of the engineering sciences. Distance is not an invariant of topology since any figure may be "stretched" to any size by a homeomorphism. For this reason it does not lend itself easily to those sciences where measurement and rigid bodies are of first importance as engineering. At the present time it finds its only application to engineering in the analysis of networks in electrical circuit theory.

The present book gives an account of the topology of plane sets and forms a carefully written introduction to the subject which may be read with no previous knowledge on the part of the reader. The first four chapters, which comprise roughly half the book, give an elegant exposition of the general theory of sets of points. The last four chapters develop the plane topology using rectangular gratings. Among other results a simple and readable proof of the Jordan curve theorem is given.

This book will serve as an excellent introduction to this im-

[4] Associate Professor of Mathematics, University of Michigan, Ann Arbor, Michigan.

portant and fascinating subject. It is to be regretted that the author seems to be unaware of the important American work in plane topology with the exception of the Alexander Lemma.

Hydrodynamics

THEORETICAL HYDRODYNAMICS. By L. M. Milne-Thomson. The Macmillan Company, New York, N. Y., 1938. Cloth, 6¼ × 9¾ in., xxv and 552 pp., 330 figs., 4 plates, and 508 exercises, $11.25.

REVIEWED BY HUGH L. DRYDEN[5]

THIS book, which is an outgrowth of the author's lectures to junior naval constructors at the Royal Naval College, is a clear account of the mathematical theory of the motion of an inviscid or perfect fluid based on vector methods and notation. A single chapter of 37 pages is devoted to viscosity. The book accordingly makes a good textbook for courses in classical fluid mechanics. Over 500 examples are provided, some easy, but many quite difficult. As indicated by the title, there is no attempt to introduce comparisons with experiment or to indicate fields of practical application.

The book contains 19 chapters. The first three deal respectively with Bernoulli's equation, properties of vectors, and general aspects of the equations of motion. Chapter 4 describes those properties of two-dimensional motion which can be treated without the complex variable. Chapter 5 gives an account of the theorems with respect to the complex variable, defined as a vector operator, required in the following treatment. The next nine chapters give a detailed discussion of two-dimensional motion in terms of the complex variable; the chapter headings are streaming motions, airfoils, sources and sinks, moving cylinders, theorem of Schwarz and Christoffel, jets and currents, the wake, rectilinear vortices, and waves. The next four chapters treat three-dimensional problems, first the application of conformal mapping to problems with axial symmetry, then, spheres and ellipsoids, solids moving through a liquid, and vortex motion in three dimensions. The final chapter gives the application of vector methods to viscous liquids.

The experience and skill of the author as a teacher have enabled him to present the subject with the detail essential to ease of comprehension of the mathematical development, yet without prolixity. While the language is mainly mathematical, the text moves along smoothly, and the physical interpretations are given, though often in very brief space. Thus the physical concept, virtual mass, is described in a single sentence on each of two widely separated pages. The author mentions one new method specifically, a method of partial differentiation with respect to a vector applied to obtain Kirchhoff's equations, and there are other original contributions and original methods of presentation throughout the text.

Strength of Materials

FORMULAS FOR STRESS AND STRAIN. By Raymond J. Roark, Professor of Mechanics, University of Wisconsin. Product Development Series, First Edition, McGraw-Hill Book Company, Inc., New York, N. Y., 1938. Cloth, 6 × 9 in., ix and 326 pp., 19 tables, 36 figs., $3.

REVIEWED BY R. E. PETERSON[6]

THIS book combines the sequence and general style of a strength-of-materials textbook and the direct usefulness of a conventional handbook. It differs from the strength-of-materials textbook in not giving the derivation of formulas and also in presenting much information not found in such a textbook. It differs from the handbooks in stating general principles, in making available the results of advanced work, in including literature references for all data, and in giving supplementary explanations and notes. It is obvious in looking over the book that it has been designed primarily to be of ready use as a reference; the tables are excellently arranged and all data are clearly and carefully presented.

In part one definitions and symbols are given.

In part two general statements are made concerning the behavior of engineering materials under various types of loading, the principles used in mathematical analysis, and the main experimental methods used for the solution of stress-distribution and strength problems.

In part three 18 tables are given together with text explanations. Tables of stresses and deflections are not usually found for such cases as curved beams, circular rings, flat plates, pressure vessels, and bodies in contact. The tables of elastic stability of a wide variety of members are also of unusual value. The table of stress-concentration factors will be especially useful to the designer. Two minor suggestions occur to the reviewer in this connection. The term "stress-concentration factor for repeated loading" can be replaced by a more accurate term which has recently come into use, namely "fatigue strength reduction factor." The data under 8 in Table 17 for fillets in tension are now obsolete and represent a considerable error. These data were obtained by Timoshenko and Dietz about fifteen years ago (among the early photoelastic tests in this country); celluloid models and white light were used at that time. The recent results of advanced technique using bakelite models and monochromatic light may be considered highly accurate. Data by Frocht (reference 6) should be used for the foregoing case. The remainder of the table contains the latest data available.

The points just mentioned are indeed quite minor when one considers the large amount of data presented. The reviewer and his associates have found the book to be useful on a number of occasions and can recommend it highly to engineers who need a ready source of information for design problems.

Diesel Engines

DIESEL ENGINES. By B. J. von Bongart. D. Van Nostrand Company, Inc., New York, N. Y., 1938. Cloth, 6 × 9 in., xiii and 335 pp., 346 figs., $5.50.

REVIEWED BY C. FAYETTE TAYLOR[7]

THIS book comprises a varied assortment of information on the modern Diesel engine. Of its 335 pages approximately 230 are devoted to rather uncritical descriptive matter of various types of Diesel engines, fuel pumps, and injection nozzles.

The theoretical portion of the book is contained in four chapters, the first of which is called "Thermodynamics," largely confined to the air cycle and to some very brief data on fuel consumption. This is followed by a brief chapter, "Combustion," giving meager and scattered information on the pressure-time diagram and the delay period. "Fuel Oils" are treated in fifteen pages, mostly devoted to laboratory characteristics, with an extremely brief consideration of ignition lag. The chapter on "Fuel Atomization" appears to be compilations of some of the results obtained by the National Advisory Committee for Aeronautics and by one or two German investigators.

At the end of the book is a chapter called "Miscellaneous," which treats of governors, cooling systems, dynamic balance, and

[7] Professor of Automotive Engineering, Massachusetts Institute of Technology, Cambridge, Mass.

vibration, all in thirteen pages. The introductory chapter on the history of the Diesel engine, however, is unusually complete.

The sources of the data presented, most of which are in the form of curves, are in many cases not given and in other cases difficult to determine. It is evident, however, that these data have been taken from the literature and are not the result of original work on the part of Mr. von Bongart. That he is somewhat biased in favor of the Diesel engine is indicated by two altitude-performance curves, Figs. 233 and 238, both of which show an advantage of the Diesel engine at altitude, which is not confirmed in practice or by any properly conducted tests (see N.A.C.A. Technical Note No. 619). These curves are extremely misleading and tend to shed doubt on the accuracy of other data in the book. Many of the other curves, unaccompanied by adequate critical analysis, tend to be difficult to understand or even misleading.

It is with regret that this reviewer must state that this book adds nothing of significant value to existing literature on the subject of the Diesel engine.

The Theory of Machines

THE THEORY OF MACHINES. By Thomas Bevan. First edition, Longmans, Green and Company, New York, N. Y., 1939. Cloth, 5½ × 9½ in., vii and 549 pp., 357 figs., $5.40.

REVIEWED BY G. B. KARELITZ[8]

BOOKS on the elementary theory of machines appear frequently. This can only mean that the profession is not satisfied with the existing textbooks. The probable reason is that the subject is practically unlimited in scope and no textbook could cover all requirements. Even a comparatively simple machine presents many problems when its performance, the forces on its members, its vibrations, etc., are analyzed. The information collected by any author must be presented in a limited number of pages; his book may therefore seem inadequate. Moreover, writers often have their pet subjects which overshadow other topics, such as gear-tooth development, or unbalanced forces in reciprocating engines. In addition, the art has moved so fast during recent years that all textbooks on machine design appear somewhat obsolete as soon as they are printed. Any new textbook on the theory of machines is therefore received with considerable interest.

The book of Bevan may be called to the attention of the profession. It was written primarily for "the student who is preparing for a university degree or who intends to sit for the membership examination of one of the engineering institutions." Its contents are therefore chosen and treated to give the student the necessary equipment to answer the problems given during these examinations. The author did a thorough job. He collected carefully the information necessary to satisfy the examiners and has given in the book numerous problems for exercise, with answers appended at the end of the volume. A large proportion of the problems are from the "examination papers" of various institutions. The problems indicate that the examiners endeavored to compile fair questions which would soundly test the familiarity of the aspirants with the theory of machines.

This approach has produced a volume which is no more advanced or modern than several of our current textbooks, but which covers the field very completely. The derivation of expressions is clear and precise while the material is presented in a concise manner. The 550 pages contain a vast store of information, and teachers of mechanics of machinery will be delighted to use this volume.

The table of contents reads as follows: Simple mechanisms; motion, inertia; velocity and acceleration; mechanisms with lower pairs; valve diagrams and valve gears; friction; belt, rope, and chain drives; brakes and dynamometers; cams; toothed gearing; gear trains; the equilibrium of machines, turning moment, the flywheel; governors; balancing; vibrations. Two thirds of the work is given to kinematics, and one third only to dynamics of machinery. However, dynamic balancing machines are briefly described and their action explained. The brief chapter on vibration covers the oscillation of a pendulum, the critical speed of a shaft and the torsional vibration of two-rotor, and multirotor shafts. As usual, the chapter on governors deals mostly with the mechanics of the flyball type.

The text is well illustrated with numerical examples which are carried out in detail. Numerous problems at the end of each chapter add greatly to the value of the book. But this volume does not obviate the need of a good modern textbook on the theory of machines, a book which would reflect the advances of recent years in machine design.

The Normal Modes of Vibrations of Beams Having Noncollinear Elastic and Mass Axes

By CLYNE F. GARLAND,[1] BERKELEY, CALIF.

This analysis deals with vibration characteristics of cantilever beams in which the longitudinal axis, passing through the mass centers of the elementary sections, is not collinear with the longitudinal axis about which the beam tends to twist under the influence of an applied torsional couple. Expressions are derived from which the natural frequencies and normal modes of vibration of such a beam can be determined. The Rayleigh-Ritz method is employed to determine the frequencies and amplitude ratios. Following the development of the general expressions, more specific equations are derived which express the natural frequencies and relative amplitudes of motion in each of two normal modes of vibration.

The theoretical relationships of the several physical properties of the beam to the natural frequencies of vibration are shown graphically. Finally a numerical example is presented for a particular beam, and the computed natural frequencies and normal modes are compared with those determined experimentally.

DURING recent years, with the development of machines for heavy-duty and high-speed service, there has come a wide interest in the many vibration problems which have arisen. Mechanical vibrations, with their accompaniment of increased stresses, energy losses, and noises, are apt to appear not only in the parts of the machine itself, but also in the structural members of its supporting framework.

A thorough understanding of the relationships among the several factors involved in vibration phenomena has become of great importance to those concerned with the design of machines. To this end expressions for the normal modes of vibration and the corresponding natural frequencies have been developed for a large number of machine parts of simple form (1, 2).[2]

The analysis here presented deals with the vibration characteristics of cantilever beams in which the longitudinal axis G, shown in Fig. 1, which passes through the mass centers of the elementary sections Δy, is not collinear with the longitudinal axis C about which the beam tends to twist under the influence of an applied torsional couple. The axis of twist C, sometimes known as the "elastic axis," may also be defined by the property that it is the only axis along which a transverse load applied to the beam will produce flexure without twisting. The condition of noncollinear axes just described is known to exist in most prismatic bars having nonsymmetrical sections (3, 4, 18), as well as in built-up beams whose structural members are not symmetrically placed (5, 6).[3]

When such a beam is subjected to a transverse vibratory motion, say in the Y-Z plane shown in Fig. 1, torsional oscillations of the beam about the longitudinal axis are caused to be superimposed upon the lateral motion. This torsional motion of any elementary length of the beam is due to the fact that the resultant of the transverse shearing forces on the section acts at C, and therefore tends to rotate the section about its mass center G. Thus, the beam is seen to behave as a coupled elastic system with normal modes of vibration involving simultaneous displacements in flexure and torsion. Accordingly, the natural frequencies of vibration in the several normal modes differ from the frequencies computed for vibration in pure flexure and pure torsion, respectively.

In the present paper general expressions are developed from which the natural frequencies and normal modes of vibration of such a beam can be determined. These expressions are derived from energy considerations which, in turn, are based upon assumed normal elastic deflection curves in bending and torsion. The Rayleigh-Ritz method is employed to determine the frequencies and amplitude ratios. Following the development of

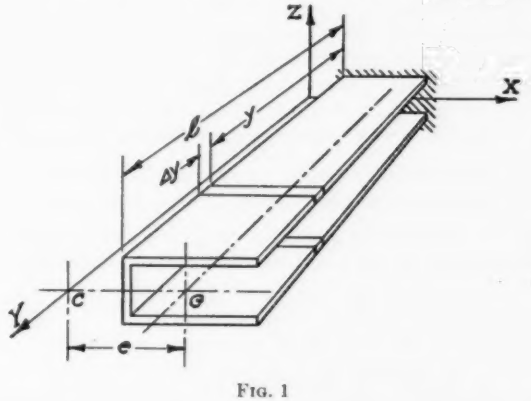

FIG. 1

the general expressions, more specific equations are derived which express the natural frequencies and relative amplitudes of motion in each of two normal modes of vibration. These equations involve dimensionless groups, the values of which depend upon the various physical characteristics of the beam. The theoretical relationships of the several physical properties of the beam to the natural frequencies of vibration are also shown graphically in Fig. 3. Finally, a numerical example is presented for a particular beam, and the computed natural frequencies and normal modes are compared with those determined experimentally.

A first approximation to the solution of this problem was made by Greene and Younger (7, 8)[4] in a study of the flutter of monoplane wings. In their solution the wing (i.e., beam) is treated as a rigid body constrained to rotate about a transverse axis at the built-in end and about a longitudinal axis—corresponding to

Presented at the Annual Meeting, Philadelphia, Pa., December 4-8, 1939, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until October 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[3] The relative positions of these axes in the airplane wing is discussed in these references.

[4] A summary of the theoretical work appears in reference (8).

the X- and Y-axes, respectively, in Fig. 1. The elastic restoring moments are taken to be proportional to the angular motion about these respective axes. Expressions are derived for the natural frequencies of vibration of this idealized wing in each of its two normal modes. A similar treatment of the same problem is presented by Kassner and Fingado (9) in which they treat the wing as a rigid body supported on springs and left free to execute up-and-down vibrations without torsion, or to undergo torsional oscillations about any longitudinal axis. Here again the system has been very highly idealized in that no attempt has been made to take into account the elastic deformations in flexure and torsion. Many other writers (11, 12, 13, 14, 15, 16)[5] who have investigated the problem of flutter in the wings and control surfaces of airplanes have been primarily interested in determining the relationship of the structural characteristics of the wing to the critical air speed at which the phenomenon of flutter is induced, and devote little or no attention to the aspect of the problem to be considered in this paper.

It may be well to note at this point that the problem considered in the present paper is related to the problem of wing flutter in that (*a*) in most cases the monoplane wing is essentially a beam of type under consideration, and (*b*) when such a wing is excited by an air stream moving at the proper (i.e., critical) velocity it tends to vibrate in one of its normal modes and at the corresponding natural frequency (7, 10, 13, 14, 16).[6] The problem of flutter is mentioned here because it has received a great amount of study due to the many spectacular and tragic aircraft accidents which have been traced to this cause. It is generally considered as an example of self-induced vibration (17),[7] a special type of vibration which is not to be confused with the more common forced-vibration phenomenon.

While the principles discussed in this paper are related to the problem of flutter to the extent outlined, it should be clearly understood that their applications are by no means limited to that particular problem. Indeed determination of the natural frequencies and normal modes is essential to the solution of any vibration problem in which such a structural member is involved.

Derivation of Expressions for the Natural Frequencies and Normal Modes—General

The free vibrations of a beam of the type shown in Fig. 1 may be considered to be the resultant of the three components

$$\left.\begin{aligned} z &= [a_1Y_1 + a_2Y_2 + a_3Y_3 + \dots.] \sin \omega_n t \\ \theta &= [\varphi_1 Y_1' + \varphi_2 Y_2' + \varphi_3 Y_3' + \dots.] \sin \omega_n t \\ x &= [b_1 Y_1'' + b_2 Y_2'' + b_3 Y_3'' + \dots.] \sin \omega_n t \end{aligned}\right\} \dots [1]$$

where z denotes the vertical component of displacement at any section; θ denotes the angular displacement at any section; x denotes the horizontal component of displacement at any section; $Y_1, Y_2, \dots Y_1', Y_2', \dots Y_1'', Y_2'', \dots$ are functions of y which satisfy the end conditions for any particular beam; and $a_1, a_2, a_3, \dots \varphi_1, \varphi_2, \varphi_3 \dots b_1, b_2, b_3, \dots$ are the amplitudes of the respective functions Y_n.

In order to reduce the complexity of the equations it will be assumed that the flexural rigidity of the beam in the X-Y plane is very much greater than that in the Y-Z plane. Thus, the x component of the motion may be neglected and the total motion considered to be composed of the z and θ components. This assumption is a reasonable one since most beams of unsymmetrical section are much stiffer in one plane than in the other.

The potential energy of the beam may then be expressed as the sum of the energies stored in the beam due to the displacements z and θ, respectively, or

$$V = \frac{EI_{x-x}}{2} \int_0^l \left(\frac{\partial^2 z}{\partial y^2}\right)^2 dy + \frac{C}{2} \int_0^l \left(\frac{\partial \theta}{\partial y}\right)^2 dy \dots [2]$$

where V is the total potential energy stored in the beam; E is Young's modulus; I_{x-x} is the rectangular moment of inertia of the beam section relative to the x-axis; C is the torsional rigidity of the beam (3, 18);[8] and l is the length of the beam.

If the expressions for z and θ from Equation [1] are substituted into Equation [2], the expression for the potential energy becomes

$$V = \frac{1}{2}\left\{EI_{x-x}\left[a_1^2 \int_0^l \left(\frac{d^2Y_1}{dy^2}\right)^2 dy + a_2^2 \int_0^l \left(\frac{d^2Y_2}{dy^2}\right)^2 dy + \dots\right] + C\left[\varphi_1^2 \int_0^l \left(\frac{dY_1'}{dy}\right)^2 dy + \varphi_2^2 \int_0^l \left(\frac{dY_2'}{dy}\right)^2 dy + \dots\right]\right\} \sin^2 \omega_n t \dots [2a]$$

or

$$V = \frac{1}{2}\left\{K_x[a_1^2Q_1 + a_2^2Q_2 + \dots] + C[\varphi_1^2 R_1 + \varphi_2^2 R_2 + \dots]\right\} \sin^2 \omega_n t \dots [2b]$$

where K_x denotes the flexural rigidity EI_{x-x}; $Q_1, Q_2, \dots$ denote the integrals $\int_0^l \left(\frac{d^2Y_1}{dy^2}\right)^2 dy$, $\int_0^l \left(\frac{d^2Y_2}{dy^2}\right)^2 dy$, ... respectively; and $R_1, R_2, \dots$ denote the integrals $\int_0^l \left(\frac{dY_1'}{dy}\right)^2 dy$, $\int_0^l \left(\frac{dY_2'}{dy}\right)^2 dy$, ... respectively. Or still more briefly

$$V = \frac{1}{2}\{\beta\} \sin^2 \omega_n t \dots [2c]$$

where β denotes the quantity in braces, Equations [2a] and [2b].

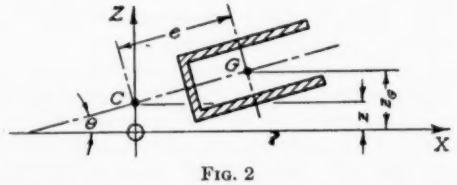

Fig. 2

Applying the principle of motion of the mass center to the elementary transverse section of the beam shown in Fig. 2, the kinetic energy of the element is expressed as the sum of the kinetic energy due to the translation of the mass center and that due to the rotation about the mass center. Thus, integrating over the length of the beam, the expression for the total kinetic energy becomes

$$T = \frac{1}{2}\rho A \int_0^l \dot{z}_G^2 dy + \frac{1}{2}\rho J_G \int_0^l \dot{\theta}^2 dy \dots [3$$

where T is the total kinetic energy at the displacement z, θ; ρ is the mass density of the material of which the beam is made; A is the cross-sectional area of the beam; z_G is the vertical displacement of the mass-center G; $\dot{z}_G$ is the z component of the

[5] For examples see references (11, 12, 13, 14, 15, 16) inclusive. The work of many others is summarized in reference (14).

[6] Discussions of experiments designed to determine the relationship of the natural frequencies of a wing to the critical air speeds are given in these references.

[7] This reference gives a discussion of the general theory of self-induced vibrations, together with a number of examples encountered in the operation of machinery.

[8] Discussions of the torsional rigidity of bars having nonsymmetrical sections are given in these references.

velocity of the mass center; $\dot{\theta}$ is the instantaneous angular velocity of rotation of the section; and J_G is the polar moment of inertia of the section with respect to the gravity axis.

From the geometry of Fig. 2, for small values of θ

$$z_G = z + e\theta \quad \text{(approximately)} \ldots\ldots\ldots\ldots [4]$$

Hence, by differentiating Equation [4] with respect to time

$$\dot{z}_G = \dot{z} + e\dot{\theta} \ldots\ldots\ldots\ldots\ldots\ldots [5]$$

Substituting this value of $\dot{z}_G$ into Equation [3] the expression for the kinetic energy becomes

$$T = \frac{1}{2}\rho A\left[\int_0^l (\dot{z}^2 + 2e\dot{z}\dot{\theta} + e^2\dot{\theta}^2)\,dy + \frac{J_G}{A}\int_0^l \dot{\theta}^2 dy\right] \ldots [3a]$$

From Equation [1], by differentiation

$$\left.\begin{aligned} \dot{z} &= (a_1Y_1 + a_2Y_2 + a_3Y_3 + \ldots.)\ \omega_n \cos \omega_n t \\ \dot{\theta} &= (\varphi_1Y_1' + \varphi_2Y_2' + \varphi_3Y_3' + \ldots.)\,\omega_n \cos \omega_n t \end{aligned}\right\} \ldots [6]$$

Substituting these values into Equation [3a]

$$\begin{aligned} T = \frac{1}{2}\rho A \Bigg\{\Bigg[& a_1^2\int_0^l Y_1^2 dy + a_2^2\int_0^l Y_2^2\,dy \\ & \ldots. 2a_1a_2\int_0^l Y_1Y_2\,dy + \ldots\Bigg] + 2e\Bigg[a_1\varphi_1\int_0^l Y_1Y_1'dy \\ & + a_1\varphi_2\int_0^l Y_1Y_2'dy + \ldots + a_2\varphi_1\int_0^l Y_2Y_1'dy \\ & + a_2\varphi_2\int_0^l Y_2Y_2'dy + \ldots + \ldots\ldots\Bigg] \\ & + \left(e^2 + \frac{J_G}{A}\right)\Bigg[\varphi_1^2\int_0^l Y_1'^2dy + \varphi_2^2\int_0^l Y_2'^2dy \\ & + \ldots 2\varphi_1\varphi_2\int_0^l Y_1'Y_2'dy + \ldots\ldots\ldots\Bigg]\Bigg\}\omega_n^2\cos^2\omega_n t \ldots [3b] \end{aligned}$$

Collecting terms, and denoting $\int_0^l Y_1^2dy$ by S_1, $\int_0^l Y_1'^2$ by $S_{1'}$, $\ldots \int_0^l Y_2^2dy$ by S_2, $\int_0^l Y_2'^2dy$ by $S_{2'}$, $\ldots$, Equation [3b] becomes

$$\begin{aligned} T = \frac{1}{2}\Bigg\{\rho A\Bigg[& (a_1^2S_1 + a_2^2S_2 + \ldots.. 2a_1a_2S_{1-2} + \ldots) \\ & + 2e(a_1\varphi_1S_{1-1'} + a_1\varphi_2S_{1-2'} + \ldots.. + a_2\varphi_1S_{2-1'} + a_2\varphi_2S_{2-2'} \\ & + \ldots.. + \ldots) + \left(e^2 + \frac{J_G}{A}\right)(\varphi_1^2S_{1'} + \varphi_2^2S_{2'} \\ & + \ldots 2\varphi_1\varphi_2S_{1'-2'} + \ldots)\Bigg]\Bigg\}\omega_n^2\cos^2\omega_n t \ldots [3c] \end{aligned}$$

or, more briefly

$$T = \frac{1}{2}\{\alpha\}\,\omega_n^2\cos^2\omega_n t \ldots\ldots\ldots\ldots [3d]$$

where α represents the quantity within the braces in Equation [3c].

Now that the expressions for the kinetic and potential energies of the beam have been determined, the natural frequencies of vibration may be evaluated by applying the Rayleigh-Ritz method. Equating the maximum values of the potential and kinetic energies, as obtained from Equations [2c] and [3d], respectively, and solving for the frequency

$$\omega_n^2 = \frac{\beta}{\alpha} \ldots\ldots\ldots\ldots\ldots\ldots [7]$$

The expressions for both β and α involve the coefficients a_1, $a_2, \ldots$, and $\varphi_1, \varphi_2, \ldots$, which define the assumed elastic deflection curves. Therefore, the values of ω_n obtained from Equation [7] depend upon the assumed curves. By Rayleigh's principle, if the assumed elastic curve is not the exact one, the lowest computed value of natural frequency will be higher than the true fundamental frequency of the beam. Or, to state it a little differently, if several elastic curves are assumed in succession, the one yielding the lowest value of frequency is nearest correct. In order to obtain the closest approximation possible, the coefficients $a_1, a_2, \ldots$, and $\varphi_1, \varphi_2, \ldots$ must be so chosen that the fundamental frequency computed from Equation [7] will be a minimum. This value of ω_n^2 may be found by equating to zero the partial derivative of β/α with respect to each of the coefficients $a_1, a_2, \ldots$, and $\varphi_1, \varphi_2, \ldots$, respectively. Thus

$$\left.\begin{aligned} \alpha\frac{\partial\beta}{\partial a_1} - \beta\frac{\partial\alpha}{\partial a_1} &= 0 \\ \alpha\frac{\partial\beta}{\partial a_2} - \beta\frac{\partial\alpha}{\partial a_2} &= 0 \\ \ldots\ldots\ldots\ldots & \\ \alpha\frac{\partial\beta}{\partial\varphi_1} - \beta\frac{\partial\alpha}{\partial\varphi_1} &= 0 \\ \alpha\frac{\partial\beta}{\partial\varphi_2} - \beta\frac{\partial\alpha}{\partial\varphi_2} &= 0 \\ \ldots\ldots\ldots\ldots & \end{aligned}\right\} \ldots\ldots\ldots\ldots [8]$$

From Equation [7] it is noted that $\beta = \omega_n^2\alpha$. Hence Equation [8] may be written in the form

$$\left.\begin{aligned} \frac{\partial\beta}{\partial a_1} - \omega_n^2\frac{\partial\alpha}{\partial a_1} &= 0 \\ \frac{\partial\beta}{\partial a_2} - \omega_n^2\frac{\partial\alpha}{\partial a_2} &= 0 \\ \ldots\ldots\ldots\ldots & \\ \frac{\partial\beta}{\partial\varphi_1} - \omega_n^2\frac{\partial\alpha}{\partial\varphi_1} &= 0 \\ \frac{\partial\beta}{\partial\varphi_2} - \omega_n^2\frac{\partial\alpha}{\partial\varphi_2} &= 0 \\ \ldots\ldots\ldots\ldots & \end{aligned}\right\} \ldots\ldots\ldots\ldots [9]$$

These equations are seen to be homogeneous and linear in the coefficients $a_1, a_2, \ldots \varphi_1, \varphi_2, \ldots$, and are equal in number to the number of coefficients. By setting the determinant of these equations equal to zero, eliminating the coefficients, and expanding, the frequency equation may be obtained. The frequency equation yields the values of the natural frequencies in the several normal modes.

The amplitude ratios $a_2/a_1, \ldots \varphi_1/a_1, \varphi_2/a_1, \ldots$, which determine the configuration of the beam in each of the normal modes, can then be evaluated by substituting the respective values of ω_n into Equations [9].

Derivation of Frequency Equation for Two Normal Modes

To illustrate the process outlined, a frequency equation yielding two natural frequencies will now be derived. As a first ap-

proximation the instantaneous displacement of the beam may be expressed by the components

$$\left.\begin{aligned} z &= a_1 Y_1 \sin \omega_n t \\ \theta &= \varphi_1 Y_1' \sin \omega_n t \\ x &= 0 \end{aligned}\right\} \quad \ldots\ldots\ldots\ldots\ldots [10]$$

where Y_1' is a function of y which satisfies the end conditions for flexure and Y_1' satisfies the end conditions for torsion.

From Equation [2b]

$$\beta = K_x a_1^2 Q_1 + C\varphi_1^2 R_1 \ldots\ldots\ldots\ldots\ldots [11]$$

and from Equation [3c]

$$\alpha = \rho A\left[a_1^2 S_1 + 2ea_1\varphi_1 S_{1-1'} + \left(e^2 + \frac{J_G}{A}\right)\varphi_1^2 S_1'\right] \ldots [12]$$

Taking partial derivatives with respect to a_1 and φ_1, respectively, and denoting $S_{1-1'}/S_1$ by η, and S_1'/S_1 by γ, the following expressions are obtained

$$\left.\begin{aligned} \frac{\partial \beta}{\partial a_1} &= 2K_x Q_1 a_1 \\ \frac{\partial \beta}{\partial \varphi_1} &= 2CR_1\varphi_1 \\ \frac{\partial \alpha}{\partial a_1} &= 2\rho A S_1[a_1 + \eta e\varphi_1] \\ \frac{\partial \alpha}{\partial \varphi_1} &= 2\rho A S_1\left[\left(e^2 + \frac{J_G}{A}\right)\gamma\varphi_1 + \eta e a_1\right] \end{aligned}\right\} \quad \ldots\ldots [13]$$

Substituting these terms into Equation [9] and rearranging into determinant form

$$\begin{vmatrix} 2[K_x Q_1 - \rho A S_1 \omega_n^2]a_1 & -2[\rho A S_1 \eta e \omega_n^2]\varphi_1 \\ -2[\rho A S_1 \eta e \omega_n^2]a_1 & 2\left[CR_1 - \rho A S_1 \gamma\left(e^2 + \frac{J_G}{A}\right)\omega_n^2\right]\varphi_1 \end{vmatrix} = 0 \ldots [14]$$

Dividing the first column by $2\rho A S_1 a_1$ and the second column by $2\rho A S_1 \varphi_1$, the determinant is reduced to the form

$$\begin{vmatrix} \frac{K_x Q_1}{\rho A S_1} - \omega_n^2 & -\eta e \omega_n^2 \\ -\eta e \omega_n^2 & \frac{CR_1}{\rho A S_1} - \gamma\left(e_2 + \frac{J_G}{A}\right)\omega_n^2 \end{vmatrix} = 0 \ldots [15]$$

At this point it may be noted that the quantity $\left[\frac{K_x Q_1}{\rho A S_1}\right]^{1/2}$ is the familiar expression for the natural frequency of flexural vibration for a uniform beam. This quantity is therefore the natural frequency of the beam under consideration for the particular case in which e is zero. For convenience the natural frequency for this particular case ($e = 0$) may be denoted by the symbol ω_0. Then, with the view to express the natural frequencies as dimensionless ratios, the relationship

$$\frac{K_x Q_1}{\rho A S_1} = \omega_0^2 \ldots\ldots\ldots\ldots\ldots [16]$$

may be substituted into Equation [15] and each term of the equation divided by ω_0^2. After this operation is performed and the determinant is expanded into linear form, simplified, and rearranged, the following quadratic equation is obtained

$$\left[\gamma\left(e^2 + \frac{J_G}{A}\right) - \eta^2 e^2\right]\left(\frac{\omega_n^2}{\omega_0^2}\right)^2 - \left[\frac{CR_1}{K_x Q_1} + \gamma\left(e^2 + \frac{J_G}{A}\right)\right]\frac{\omega_n^2}{\omega_0^2} + \frac{CR_1}{K_x Q_1} = 0 \ldots [17]$$

Introducing the additional dimensionless quantities

$$\lambda = \frac{CR_1 A}{K_x Q_1 \gamma J_G} \ldots\ldots\ldots\ldots [18]$$

$$\text{and } \epsilon = \frac{e^2 A}{J_G} \ldots\ldots\ldots\ldots [19]$$

and dividing by $\frac{\gamma J_G}{A}$, Equation [17] is further simplified to the form

$$\left[\epsilon\left(1 - \frac{\eta^2}{\gamma}\right) + 1\right]\left(\frac{\omega_n^2}{\omega_0^2}\right)^2 - (\lambda + \epsilon + 1)\frac{\omega_n^2}{\omega_0^2} + \lambda = 0 \quad [20]$$

This is the *frequency equation* and its two roots are

$$\frac{\omega_1^2}{\omega_0^2} = \frac{(\lambda + \epsilon + 1) - \sqrt{(\lambda + \epsilon + 1)^2 - 4\lambda\left[\epsilon\left(1 - \frac{\eta^2}{\gamma}\right) + 1\right]}}{2\left[\epsilon\left(1 - \frac{\eta^2}{\gamma}\right) + 1\right]} \quad \ldots\ldots [21]$$

$$\text{and } \frac{\omega_2^2}{\omega_0^2} = \frac{(\lambda + \epsilon + 1) + \sqrt{(\lambda + \epsilon + 1)^2 - 4\lambda\left[\epsilon\left(1 - \frac{\eta^2}{\gamma}\right) + 1\right]}}{2\left[\epsilon\left(1 - \frac{\eta^2}{\gamma}\right) + 1\right]} \quad \ldots\ldots [22]$$

The physical significance of the terms λ and ϵ may now be considered. Referring to Equation [18] it is seen that, of the terms on the right-hand side, the quantities C, A, and J_G are independent of the length of the beam. From the definitions stated following Equations [2b] and [3b], Q_1 is seen to vary inversely with l^3, R_1 inversely with l, and S_1' (i.e., γS_1) directly with l. Hence λ varies with l^2, and may therefore be appropriately called the *length modulus*. Referring to Equation [19], the term ϵ, on the other hand, is seen to be entirely independent of the length and to vary with the square of e, the distance between the gravity axis and the elastic axis of the beam. Since ϵ serves as a measure of the relative positions of the two axes, for lack of a more appropriate term, it will be referred to as the *eccentricity modulus*.

Discussion of the Frequency Diagram

Fig. 3 shows the relationship of the moduli ω_n/ω_0, ϵ, and λ for a limited range of ϵ, six selected values of λ, and the particular value of $\eta^2/\gamma = 0.925$.[9] Each of the curves illustrates the variation of the natural frequencies with ϵ for a particular value of λ, as defined by Equations [21] and [22]. For positive values of ϵ any given ordinate is seen to intersect each of the λ curves in two points. The values of ω_n/ω_0 at these two points of intersection determine the natural frequencies of the two normal modes.

[9] The value of η^2/γ depends upon the functions Y_1 and Y_1' which are chosen to express the elastic curves of the beam in flexure and torsion. The value used here (0.925) is taken from the numerical example presented later. A consideration of functions other than those used in the example indicates that the value of η^2/γ is quite close to 0.925, regardless of the functions chosen.

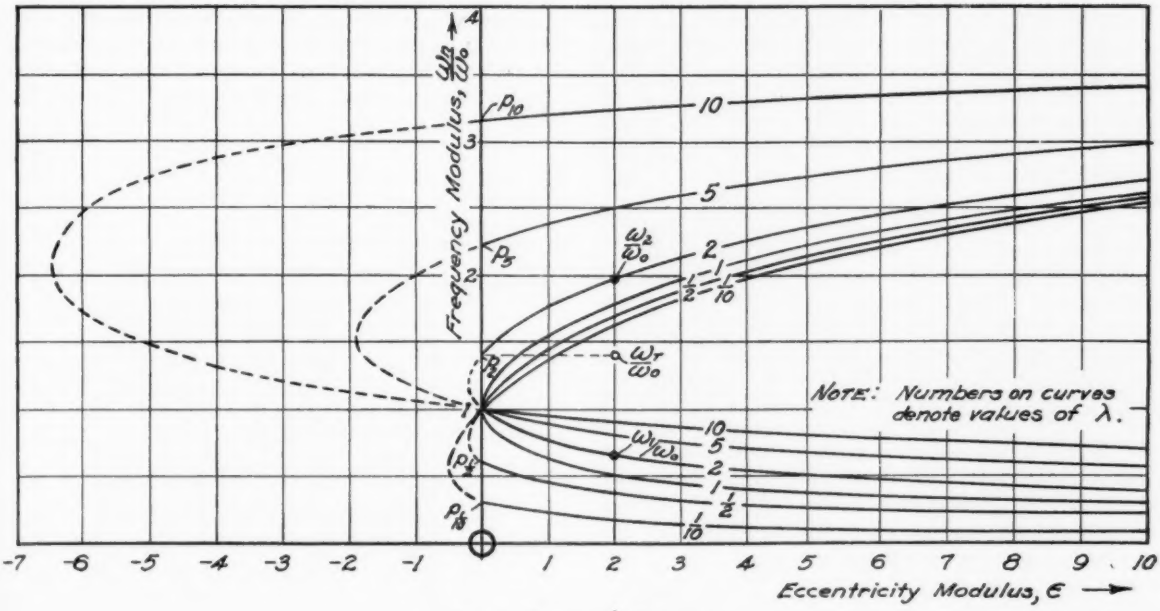

FIG. 3 FREQUENCY DIAGRAM

The dashed portions of the curves, to the left of the origin, have no physical significance. This may be concluded from the fact that, in any actual beam, the quantities e^2, A, and J_G must be real and positive. Hence a value of ϵ, as computed from Equation [19], can never be negative.

Inspection of the diagram also indicates that, for any given length modulus λ, the two natural frequencies become farther and farther apart as the eccentricity increases. Also, for a given amount of eccentricity, the difference between the two frequencies increases slightly with increasing values of λ.

It will be noted also that each of the curves passes through the point $\omega_n/\omega_0 = 1.0$, $\epsilon = 0$. This is explained by the fact that in the actual beam, if $e = 0$, one of the normal modes of vibration is that of pure flexure, and the corresponding natural frequency is ω_0. Therefore, this common point of intersection of the λ curves represents the frequency of the purely flexural vibrations which prevail in one of the normal modes when $e = 0$.

The other intersections (marked p_{10}, p_5, etc.) of the λ curves with the frequency axis have an interesting significance. Our knowledge of the fact that when $e = 0$ the normal modes of vibration of the beam are those of pure flexure and pure torsion, coupled with the fact that $\omega_n/\omega_0 = 1.0$, $\epsilon = 0$, represents the flexural mode, suggests that these points p may represent the frequency of the purely torsional mode of vibration for the case $e = 0$. Indeed such may be demonstrated to be the case.

First it will be noted that when $\epsilon = 0$ is substituted into Equations [21] and [22], the two values of ω_n/ω_0 become 1.0 and $\lambda^{1/2}$, respectively. Next, the expression for the natural frequency of the purely torsional mode of vibration may be determined by equating the maximum values of potential energy and kinetic energy for the θ component of motion. From Equation [2b] the maximum potential energy in the twisted beam is found to be

$$V_{max} = \frac{C}{2}\varphi_1^2 R_1 \quad \ldots\ldots\ldots\ldots\ldots\ldots [23]$$

From Equation [3c] the maximum kinetic energy of rotation is

$$T_{max} = \frac{1}{2}\rho S_1' J_G \varphi_1^2 \omega_n^2 \quad \ldots\ldots\ldots\ldots\ldots\ldots [24]$$

Equating V_{max} to T_{max}, substituting γS_1 for S_1', and solving for the frequency, there results the expression

$$\omega_T^2 = \frac{CR_1}{\rho J_G \gamma S_1} \quad \ldots\ldots\ldots\ldots\ldots\ldots [25]$$

where the subscript T is used to denote the torsional mode.

To put Equation [25] into dimensionless form, the left-hand side may be divided by ω_0^2, and the right-hand side by its equivalent, as defined in Equation [16]. Thus

$$\frac{\omega_T^2}{\omega_0^2} = \frac{CR_1}{\rho J_G \gamma S_1} \Big/ \frac{K_x Q_1}{\rho A \gamma S_1} = \frac{CR_1 A}{K_x Q_1 \gamma J_G} \quad \ldots\ldots\ldots [26]$$

But, referring to Equation [18], it is seen that the last quantity in Equation [26] is equal to λ. Hence, the torsional frequency is given by the expression

$$\frac{\omega_T}{\omega_0} = \lambda^{1/2} \quad \ldots\ldots\ldots\ldots\ldots\ldots [27]$$

It has been shown already that the values of the ordinates at the points p shown in Fig. 3 are equal to $\lambda^{1/2}$. Therefore, it is concluded that at these points the frequencies are those of the torsional mode of vibration of the beam when $e = 0$.

Thus the diagram indicates the ratios of the true natural frequencies (for $e \neq 0$) to the frequencies in both flexure and torsion when $e = 0$. From these ratios an estimate can be made of the accuracy to be expected of frequency computations in which the effect of e is neglected. Consider, for example, a beam in which $\lambda = 2$ and $\epsilon = 2$. From Fig. 3 it is seen that the true natural frequency ω_1 is about two thirds the value computed for purely flexural vibrations, and the second natural frequency, ω_2, is about one and one half times that computed for the case of pure torsional vibrations. Thus, it is seen that computations of critical frequencies of such a beam, in which the effect of the eccentricity e is neglected, are apt to lead to quite erroneous results.

Still another interesting characteristic of the system is indicated by the relative positions of the points p for the several values of λ. For values of λ greater than unity the points p lie above the value $\omega_n/\omega_0 = 1.0$, whereas for value of λ less than unity the corresponding points lie below the value $\omega_n/\omega_0 = 1.0$. The

interpretation of this is simply that when λ is greater than unity the critical frequency for the torsional mode of vibration is greater than that for the flexural mode, and conversely, when λ is less than unity the critical frequency in torsion is less than that in flexure. It is interesting to note also that, for the borderline case (i.e., for $\lambda = 1.0$), the natural frequencies in the flexural and torsional modes are equal.

Remarks on the Accuracy of the Method

Before terminating the discussion of the frequency curves in Fig. 3 it would seem desirable to say a word about the accuracy of the equation which they represent. It will be recalled by referring to Equation [10] that each of the assumed elastic curves was expressed as a single function of y. It is recognized that by using additional terms in the expressions for z and θ, it is possible to determine the lower frequencies with greater accuracy, and at the same time obtain approximate values of frequency for modes of higher order. For example, if two terms are used in each of the expressions for the elastic curves, the resulting frequency equation is a biquadratic from which four values of frequency can be found.

An estimate of the accuracy of the method may be gained by comparing the results which it gives with those obtained by exact solutions, for cases in which the latter are known. In applying the method to the determination of the natural frequencies of a vibrating string, Timoshenko (1) demonstrates that when only one term is used to express the assumed elastic curve, the computed value for the fundamental frequency differs from the exact value by 0.66 per cent. By using two terms the error in the computed fundamental frequency is reduced to 0.001 per cent. Again, by using three terms, the frequency of the third mode of vibration is computed with an error of less than 0.5 per cent. In another example—the case of a vibrating wedge of constant width, with the thick end built in and the other end free—Timoshenko (1) demonstrates that the error in the computed value of the fundamental frequency is about 3 per cent when only one term is used to express the elastic curve, and less than 0.1 per cent when two terms are used.

Thus it is seen that the method gives very satisfactory results, even when only a few terms are used. This statement is substantiated further by the agreement between the computed and measured frequencies found in the numerical example to follow. Since it is usually the fundamental or, in some instances, the second mode of vibration which is apt to give rise to trouble in the practical case, it is seldom necessary to use more than one term or, at most, two terms in each of the expressions for the elastic curves. Moreover, it should be recognized that when a larger number of terms is used, the extra labor of computation may not be worth the increased accuracy to be gained.

The Normal Modes of Vibration

The natural frequencies of vibration of the beam having been determined, the corresponding normal modes may now be considered. By a "normal mode" (19)[10] is meant a motion of the beam in which every particle executes simple harmonic motion and moves in phase with every other particle. Thus, all particles reach their extreme positions simultaneously and attain their maximum velocities (at their respective positions of rest) simultaneously. Such modes of motion are expressed in Equation [1] and are determined by the relative values of the amplitudes $a_1, a_2, \ldots \varphi_1, \varphi_2, \ldots$ The absolute amplitudes are of course arbitrary since they depend upon the initial displacement of the beam.

[10] A discussion of normal modes of vibration is given in reference (19), pp. 153 and 328.

As stated previously, the relative amplitudes of the assumed elastic curves can be determined from Equation [14] by first substituting for ω_n the values of natural frequency obtained from the frequency equation. Thus the amplitude ratios are found to be

$$\frac{\varphi_1}{a_1} = \frac{K_z Q_1 - \rho A S_1 \omega_n^2}{\eta \rho A S_1 e \omega_n^2} \quad [28]$$

Dividing both the numerator and the denominator of the right-hand side by $\rho A S_1$, and substituting Equation [16], Equation [28] becomes

$$\frac{\varphi_1}{a_1} = \frac{\omega_0^2 - \omega_n^2}{\eta e \omega_n^2} \quad [29]$$

When both sides of Equation [29] are multiplied by ηe, the following dimensionless equation is obtained

$$\frac{\eta e \varphi_1}{a_1} = \frac{1 - (\omega_n^2/\omega_0^2)}{(\omega_n^2/\omega_0^2)} \quad [30]$$

Equation [30] yields two values of the amplitude ratio—one for each of the values of ω_n/ω_0. It will be recalled by referring to Fig. 3 that the lower value of ω_n/ω_0 lies between zero and 1.0, while the higher value is greater than 1.0. Thus, for the first mode, $\omega_n^2/\omega_0^2 < 1.0$, and from Equation [30], $\eta e \varphi_1/a_1 > 0$. Similarly, for the second mode, $\omega_n^2/\omega_0^2 > 1.0$, and from Equation [30], $-1.0 < \eta e \varphi_1/a_1 < 0$.

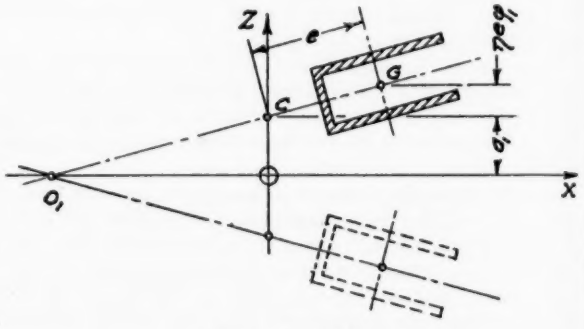

Fig. 4 First Mode

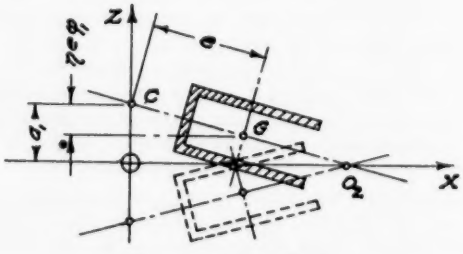

Fig. 5 Second Mode

The relative positions of the elastic axis C, and the mass axis G, at any given section of the beam, are illustrated in Figs. 4 and 5 for the first and second modes of vibration, respectively. In the first mode the nodal point at a given section lies at O_1, in Fig. 4, to the left of C. The motion of the beam at this section is therefore a harmonic oscillation about O_1. Similarly, in the second mode any given section of the beam oscillates about O_2 in Fig. 5. Since z and θ increase from zero at $y = 0$, to a_1 and φ_1, respectively, at $y = l$, according to the shapes of the assumed elastic curves in flexure and torsion, the lines passing through all the points

0_1 and all of the points 0_2, respectively, for the consecutive beam sections, form curves in the X, Y plane. Each of these curves intersects the elastic axis of the beam at the fixed end.

Experimental Work

A beam of the type shown in Fig. 1 was made by forming a strip of 24-gage cold-rolled steel into a channel with $^1/_8$-in. web and 1-in. flanges. One end of this channel was then cast into a base and mounted upon a vertical sliding head as shown in Fig. 6.

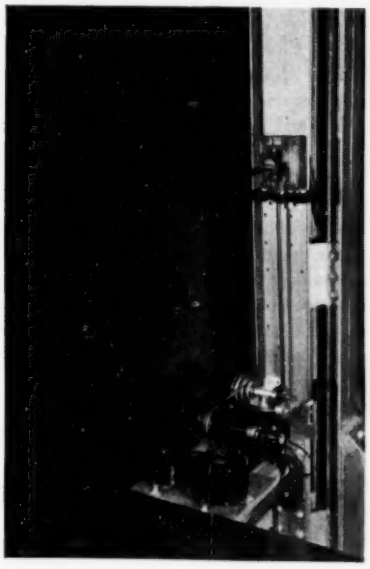

Fig. 6 Experimental Apparatus

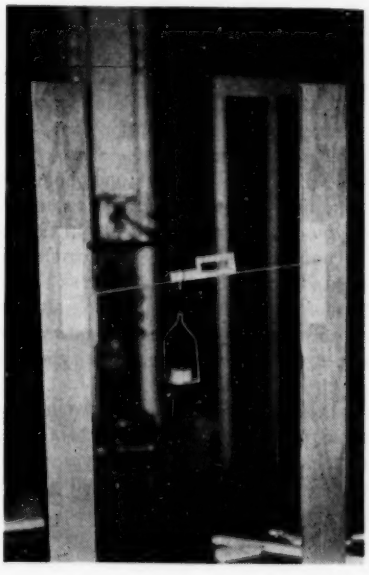

Fig. 7 Loading Frame

At the free end of the beam known loads were applied at various distances from the longitudinal axis by means of the loading device shown in Fig. 7. Lateral and torsional deflections of the beam were measured for various loads placed at several positions and from these data were determined the flexural rigidity

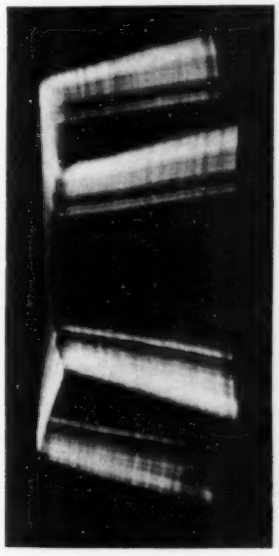

Fig. 8 First Mode, 710 Vibrations per Min

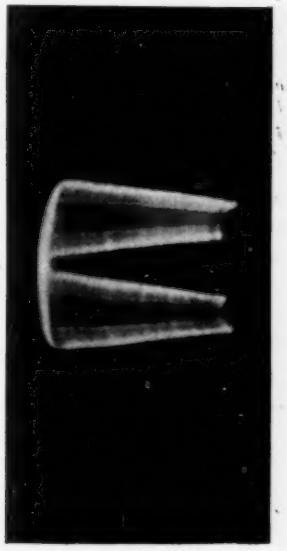

Fig. 9 Second Mode, 2600 Vibrations per Min

EI_{z-z}, the torsional rigidity C, and the location of the axis of twist. These values are used in the numerical solution which follows.

The base (i.e., the fixed end) of the beam was then caused to vibrate with small amplitude (0.018 in.) along the vertical axis by means of the driving mechanism shown in Fig. 6. The frequency of vibration was varied over a wide range and the resonant frequencies noted. A stroboscope was used to measure the frequency of vibration and also to study the nature of the motion. Marked resonant vibrations were found to occur at frequencies of 710 and 2600 vibrations per minute.

Figs. 8 and 9 are the results of time exposures which were made while the beam was vibrating in the steady state at the first and second resonant speeds, respectively. These illustrations show the configurations of the free end of the beam in the two modes.

A comparison of Figs. 8 and 9 with Figs. 4 and 5, respectively, indicates excellent agreement of predicted and observed normal modes. Furthermore, as will be shown by the numerical computations to follow, the computed natural frequencies agree quite satisfactorily with the resonant frequencies obtained by experiment.

Numerical Example

The results of the numerical solution for the two natural frequencies of the beam just described are presented in the following summary. The frequencies are computed from Equations [21] and [22]. The physical constants of the beam (a cross section is shown in Fig. 10) are

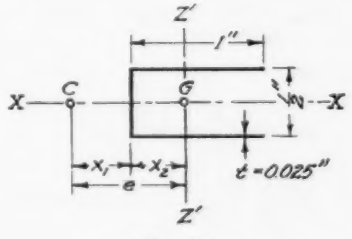

Fig. 10

l	= 40 in.	x_1	= 0.45 in. (measured)
t	= 0.025 in.	x_2	= 0.41 in. (computed)
A	= 0.0625 in.^{2}	e	= 0.86 in.
ρ	= 0.000818 lb sec^2/in.^{4}	ϵ	= 4.49
I_{x-x}	= 0.00379 in.^{4}	C	= 302 in-lb/radian/in.
I_{s-s}	= 0.00651 in.^{4}	K_x	= 116,300 lb-in.^{2}
J_θ	= 0.0103 in.^{4}		

As a first approximation the shape of the elastic curve of the beam in flexure will be expressed by

$$Y_1 = \frac{28}{27} - \cos\frac{\pi y}{2l} - \frac{1}{27}\cos\frac{3\pi y}{2l} \quad \text{[31]}$$

This function satisfies the end conditions of the beam since, at $y = 0$, $Y_1 = 0$ and $dY_1/dy = 0$; and at $y = l$, $d^2Y_1/dy^2 = 0$ and $d^3Y_1/dy^3 = 0$.

The elastic curve in torsion will be expressed by

$$Y_1' = \sin\frac{\pi y}{2l} \quad \text{[32]}$$

This function is seen to satisfy the end conditions since at $y = 0$, $y_1' = 0$ and dY_1'/dy is finite; and at $y = l$, $dY_1'/dy = 0$.

These values of Y_1 and Y_1' yield the following terms for use in the frequency equation

$$S_1 = \int_0^l Y_1^2 dy = 0.271l$$

$$Q_1 = \int_0^l \left(\frac{d^2Y_1}{dy^2}\right)^2 dy = \frac{3.376}{l^3}$$

$$S_{1-1'} = \int_0^l Y_1 Y_1' dy = 0.3538l$$

$$S_{1'} = \int_0^l Y_1'^2 dy = \frac{l}{2}$$

$$R_1 = \int_0^l \left(\frac{dY_1'}{dy}\right)^2 dy = \frac{1.234}{l}$$

$$\eta = \frac{S_{1-1'}}{S_1} = 1.305$$

$$\gamma = \frac{S_{1'}}{S_1} = 1.845$$

$$\frac{\eta^2}{\gamma} = 0.925$$

By Equation [18]

$$\lambda = \frac{CR_1A}{K_xQ_1\gamma J_G} = 3.12\,l^2 = 5.0$$

and by Equation [16]

$$\omega_0^2 = \frac{K_xQ_1}{\rho AS_1} = \frac{2.82 \times 10^{10}}{l^4}$$

$$\omega_0 = \frac{1.68 \times 10^5}{l^2} = 105 \text{ radians per sec}$$

$$N_0 = \omega_0 \times \frac{60}{2\pi} = 1003 \text{ vibrations per min}$$

Substituting these values into Equations [21] and [22], the frequency ratios are found to be

$$\left(\frac{\omega_1}{\omega_0}\right)^2 = 0.51 \qquad \frac{\omega_1}{\omega_0} = 0.71$$

$$\left(\frac{\omega_2}{\omega_0}\right)^2 = 7.36 \qquad \frac{\omega_2}{\omega_0} = 2.71$$

Multiplying these values by the value of N_0, the computed natural frequencies of the beam are

$$N_1 = 0.71 \times 1003 = 712 \text{ vibrations per min}$$

and $$N_2 = 2.71 \times 1003 = 2720 \text{ vibrations per min}$$

A comparison of these computed values with the resonant frequencies (710 and 2600 vibrations per min) indicates that the derived frequency equation gives quite satisfactory results. The computed and observed values agree almost exactly for the first mode, and differ by less than 5 per cent for the second mode.

Summary and Conclusions

The normal modes of vibration of the particular type of beam under consideration have been shown to consist of simultaneous vibrations in flexure and torsion. Each of these normal modes is characterized by a particular natural frequency and by a definite configuration of the beam. These normal modes are expressed in general form by Equation [1].

Equations [21], [22], and [30] express the natural frequencies and the corresponding amplitude ratios in terms of suitable physical constants of the beam, for the first and second normal modes of vibration. Although it is recognized that it is most frequently one or the other of these two modes which underlies vibration problems, the method of extending the solution to include the higher modes of vibration has been indicated.

The effect of the eccentricity, i.e., the displacement of the mass axis from the elastic axis, upon the natural frequencies of the beam is illustrated in Fig. 3. From this figure it is seen that the fundamental frequency becomes greater and the frequency in the second mode becomes less as the amount of the eccentricity is increased.

From a study of Fig. 3 it is also concluded that if values for the frequencies in the purely flexural and purely torsional modes of vibration are computed on the assumption that the effect of the eccentricity is negligible, the lower of these two computed values will be somewhat higher than the true fundamental frequency of the beam, and the higher of the computed values will be somewhat lower than the true natural frequency in the second mode. The error in the computed values which is introduced by such an assumption is apt to be quite large—as much as 50 per cent in the case cited. Therefore, it would seem advisable always to take the eccentricity into account in computing the natural frequencies of machine parts or structural members of the type treated in this analysis.

The excellent agreement of the natural frequencies and normal modes of vibration, as computed from the theoretical equations, with the values determined experimentally indicates that the frequency equation can be expected to yield quite satisfactory results for the two modes considered.

The frequency diagram in Fig. 3 may be used to evaluate the first two natural frequencies of a beam for which the values of ϵ, λ, and ω_0 have been computed.

The method used in this analysis takes into account the elastic deformations of the beam in flexure and in torsion, and therefore yields closer approximations to the correct values of the natural frequencies and amplitude ratios than those obtained by treating the beam as a rigid body. Any desired degree of accuracy can be attained by using a sufficient number of terms in the expressions

for the elastic deformation curves. However, for most practical problems, satisfactory values may be obtained by using only one or two terms to express each of the elastic curves.

By choosing the functions $Y_1, Y_2, \ldots Y_1', Y_2', \ldots$ in Equation [1] to satisfy the end conditions, the method can be applied to a beam with any type of support or any load distribution.

Strengthening Cylindrical Tanks of Variable Thickness Under External Pressure by Circular Stiffening Rings

By C. B. BIEZENO[1] and J. J. KOCH,[2] DELFT, NETHERLANDS

In a previous paper[3] the authors discussed the buckling of a cylindrical tank of variable thickness under external pressure, and they developed a method by which the factor of safety against buckling was derived in numerical terms.

This present paper deals with the strengthening of a tank whose factor of safety is insufficient. Obviously, great help may be expected from one or two stiffening circular rings, adjusted in the upper part of the tank, where the thickness of the shell is small. The authors show how to calculate such rings.

THE strengthening against buckling of a cylindrical tank of variable thickness under external pressure by circular stiffening rings cannot be understood unless one has at his disposal the method previously developed by the authors.[3] The method is also discussed at great length in "Technische Dynamik."[4]

It is outlined briefly under the following subhead.

1—The Differential Equations of the Buckling Problem of a Cylinder of Constant Thickness h, Subjected to the Radial Pressure q

If a be the radius of the middle surface of the cylinder, l its height, φ and z the azimuthal and axial coordinates of one of its points, u, v, w the radial, tangential, and axial displacements of this point, and q represents the radial pressure per unit surface, then with the abbreviations

$$\left.\begin{aligned} &a\frac{\partial u}{\partial z}=u';\ a\frac{\partial v}{\partial z}=v';\ a\frac{\partial w}{\partial z}=w';\ \frac{\partial u}{\partial\varphi}=u^{\cdot};\ \frac{\partial v}{\partial\varphi}=v^{\cdot};\\ &\frac{\partial w}{\partial\varphi}=w^{\cdot};\ \frac{1}{m}=\nu;\ A=\frac{Eh^3}{12(1-\nu^2)};\ B=\frac{Eh}{1-\nu^2};\\ &\frac{A}{a^2B}=\frac{h^2}{12a^2}=k;\ \frac{qa}{B}=q_1 \end{aligned}\right\}\quad[1]$$

the differential equations of the problem may be written as follows

$$\left.\begin{aligned} &u+v^{\cdot}+\nu w'+k\left[u^{\cdot\cdot\cdot\cdot}+2u^{\prime\prime\cdot\cdot}+u^{\prime\prime\prime\prime}+2u^{\cdot\cdot}+u\right.\\ &\left.-\frac{3-\nu}{2}v^{\prime\prime\cdot}+\frac{1-\nu}{2}w^{\prime\cdot\cdot}-w^{\prime\prime\prime}\right]+q_1[u+u^{\cdot\cdot}+w']=0\\ &u^{\cdot}+v^{\cdot\cdot}+\frac{1-\nu}{2}v''+\frac{1+\nu}{2}w^{\prime\cdot}+k\left[-\frac{3-\nu}{2}u^{\prime\prime\cdot}\right.\\ &\left.+\frac{3}{2}(1-\nu)v''\right]=0\\ &\nu u'+\frac{1+\nu}{2}v^{\prime\cdot}+\frac{1-\nu}{2}w^{\cdot\cdot}+w''+k\left[\frac{1-\nu}{2}u^{\prime\cdot\cdot}-u'''\right.\\ &\left.+\frac{1-\nu}{2}w^{\cdot\cdot}\right]-q_1w^{\cdot\cdot}=0 \end{aligned}\right\}\quad[2]$$

Restricting ourselves to the special case for which the radial and tangential displacements at the edges ($z=0$ and $z=l$) of the cylinder are equal to zero, we may put

$$\left.\begin{aligned} u&=U\cos p\varphi\sin\lambda(z/a)\\ v&=V\sin p\varphi\sin\lambda(z/a)\\ w&=W\cos p\varphi\cos\lambda(z/a) \end{aligned}\right\}\quad[3]$$

where p is a positive integer, $\lambda=n\pi(a/l)$; n is a positive integer, and U, V, and W are constants. Under the condition of loading prevailing in actual practice, and considering that a is very great with respect to h and of the same order as l, it may be expected that, at the moment of buckling, the number of circumferential waves is great with respect to the number of longitudinal waves, so that $\lambda^2/p^2\ll 1$.

By this remark it is possible to compare the order of magnitude of the different terms in Equation [2], and it can be shown that these equations reduce themselves, as far as u is concerned, to

$$u^{::::}+\frac{1-\nu^2}{k}u^{\prime\prime\prime\prime}+\frac{q_1}{k}u_0^{:::}=0\quad[4]$$

2—The Differential Equations of the Buckling Problem of a Tank Built Up of a Number of Cylinders Each of Constant Thickness h

If a tank is built up of a number of cylinders each of constant thickness, Equations [3] can no longer be used because they do not satisfy the boundary conditions laid upon the different cylinders. Therefore we put now

$$\left.\begin{aligned} u&=U\cos p\varphi\\ v&=V\sin p\varphi\\ w&=W\cos p\varphi \end{aligned}\right\}\quad[5]$$

where p is a positive integer, and U, V, W represent unknown functions of z, which for different rings are different and which replace the expressions $U\sin\lambda(z/a)$, $V\sin\lambda(z/a)$, $W\cos\lambda(z/a)$ (U, V, W are constant in Equations [3]). Reasoning, similar to that from section 1, now leads to

$$U''''+\frac{p^6(kp^2-q_1)}{1-\nu^2}U=0\quad[6]$$

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until October 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

As a matter of fact it is impossible to satisfy all boundary conditions imposed on the tank problem, now that the system given by Equations [2] has been reduced to a system of n differential equations of the type [6]. Therefore it has to be investigated which of these conditions can be maintained, which of them must be neglected, and eventually which of them must be softened.

Without proof we state that our buckling problem is as follows:

Calculate the minimum value of q (or q_1) which allows a solution different from $U = 0$ of the differential equations

$$U_i'''' + \frac{p^6(k_i p^2 - q_{1,i})}{1 - \nu^2} U_i = 0 \quad \ldots\ldots\ldots\ldots [7]$$

where $i = 1, 2 \ldots\ldots n$, and n represents the number of cylinders with constant thickness under the following conditions:

$$\left.\begin{array}{c} U_1 = 0;\ U_1'' = 0 \\ \text{at the upper rim of the top cylinder} \\ U_n = 0;\ U_n'' = 0 \\ \text{at the lower rim of the bottom cylinder} \\ U_i = U_{i+1};\ U_i' = U'_{i+1};\ S_{ii}U_i'' = S_{i,i+1}U''_{i+1}; \\ S_{ii}U_i''' = S_{i,i+1}U'''_{i+1};\ (i = 1, 2 \ldots n-1) \\ \text{at every joint of two consecutive rings, with} \end{array}\right\} [8]$$

$$S_{i,i} = Eh_i \quad \ldots\ldots\ldots\ldots\ldots [9]$$

3—The Substitute Bar

The foregoing formulation of our problem suggests its identification with the problem of an elastically supported bar composed of n segments. If the flexural rigidity of such a segment per unit of width be denoted by S_i $(i = 1, 2 \ldots n)$, its coefficient of elastical support per unit of width by κ_i $(i = 1, 2 \ldots n)$, its load per unit of length by r_i $(i = 1, 2 \ldots n)$, and its deflection by y_i $(i = 1, 2 \ldots n)$ then its differential equation runs

$$S_i \frac{d^4 y_i}{dz^4} + \kappa_i y_i = r_i \quad \ldots\ldots\ldots\ldots\ldots [10]$$

so that, by putting $r_i = 0$ and noticing that $a(dU/dz) = U'$, Equations [7] and [10] can be identified by requiring $S_i = s_i a^4$ and $\kappa_i = s_i \dfrac{p^6(k_i p^2 - q_{1,i})}{1 - \nu^2}$.

It can be proved that the value of the factor of proportionality s_i amounts to

$$s_i = \frac{Eh_i}{a^2 p^4}$$

so that

$$\left.\begin{array}{l} S_i = \dfrac{Eh_i a^2}{p^4} \\ \kappa_i = \dfrac{Eh_i^3 p^4}{12(1-\nu^2)a^4} - \dfrac{p^2}{a} q \end{array}\right\} \quad \ldots\ldots\ldots\ldots [11]$$

The boundary conditions of Equations [8] for the quantities U_i translate themselves into homogeneous conditions for the quantities y_i, if only S_{ii} and U_i be replaced by S_i and y_i. Therefore the buckling problem of the tank can finally be identified with the following bar problem:

A bar of unit width fixedly supported (but not clamped) at its ends consists of n segments of the length l_i $(i = 1, 2 \ldots n)$ each of which has its own flexural rigidity and its own coefficient of elastic support κ_i given by Equations [11]. If p be restricted to positive integer numbers, the minimum value of q is required, for which an equilibrium deflection, different from zero, is possible under the sole action of the elastic support.

4—The Buckling Criterion

From now we restrict ourselves to the case that the tank consists of four cylinders of constant thickness. Consequently the substitute bar consists of four parts I, II, III, IV, such as represented in Fig. 1, each having its own coefficient of flexural rigidity,

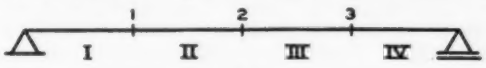

Fig. 1

and its own coefficient κ of elastic support. (The segment I of the bar represents the top cylinder of the tank, while the segment IV represents the bottom cylinder.) As the thickness of the tank increases from top to bottom, it is clear that the coefficient κ of elastic support of the different bar segments increases from left to right if p and q have fixed (but for the rest arbitrary) values, and it is to be expected that κ changes from a negative value for bar I into a positive one for bar IV. It cannot be predicted how many of the left-hand bars will have a negative κ; therefore a plausible assumption (which has to be checked a posteriori) must be made in every special case. It will be supposed that κ_{I} and κ_{II} are negative and κ_{III} and κ_{IV} positive. Instead of tackling the buckling problem in a direct way, an indirect method is followed by calculating the forces P_1, P_2, P_3, which have to be applied at the joints 1, 2, 3 of the bars I and II, II and III, III and IV if in those same points prescribed deflections y_1, y_2, y_3 have to be produced.

Formally the equations relating P_1, P_2, P_3 to y_1, y_2, y_3 may be written in the form

$$\left.\begin{array}{l} P_1 = a_{11}y_1 + a_{12}y_2 + a_{13}y_3 \\ P_2 = a_{21}y_1 + a_{22}y_2 + a_{23}y_3 \\ P_3 = a_{31}y_1 + a_{32}y_2 + a_{33}y_3 \end{array}\right\} \quad \ldots\ldots\ldots\ldots [12]$$

where the a_{ij} represent the so-called "inverse Maxwell numbers."

The mechanical significance of these numbers follows from Equations [12] themselves. Put $y_2 = 1$, $y_1 = y_3 = 0$; then

$$P_1 = a_{12} \quad P_2 = a_{22} \quad P_3 = a_{32}$$

Therefore a_{12}, a_{22}, a_{32} represent those forces which have to be applied in the points i $(i = 1, 2, 3)$ if a forced deflection y_j of unit magnitude at the point $j = 2$ and a deflection $y_j = 0$ at all other points $j \neq 2$ is prescribed.

It can be easily proved that the "inverse" Maxwell numbers are "reciprocal" like the Maxwell numbers themselves, i.e., $a_{ij} = a_{ji}$. Several problems can be treated in a natural way by the use of such numbers.[5]

As buckling of the tank requires bending of the bar not subjected to external forces, buckling only occurs if the right-hand sides of Equations [12] prove to be zero, i.e., if

$$\left.\begin{array}{l} a_{11}y_1 + a_{12}y_2 + a_{13}y_3 = 0 \\ a_{21}y_1 + a_{22}y_2 + a_{23}y_3 = 0 \\ a_{31}y_1 + a_{32}y_2 + a_{33}y_3 = 0 \end{array}\right\} \quad \ldots\ldots\ldots\ldots [13]$$

Therefore the condition of buckling is expressed by

$$\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix} = 0 \quad \ldots\ldots\ldots\ldots [14]$$

For any chosen value of p this transcendental equation in q has an infinity of roots $q^{(p)}$, the smallest of which may be designated

[5] "Technische Dynamik," by C. B. Biezeno and R. Grammel, Julius Springer, Berlin, Germany, 1939, p. 95.

by $q^{(p)}_{\min}$. The smallest value of all possible $q^{(p)}_{\min}$ ($p = 1, 2, \ldots$) represents the smallest buckling pressure of the tank.

How the coefficients a_{ij} in Equations [13] can be calculated in a practical way, and how the smallest root $q^{(p)}_{\min}$ of Equation [14] can be determined, has been described in the previous article.[3]

5—The Strengthening Effect of Circular Rings

A new question arises when for a prescribed value of the external pressure q the coefficient of safety s against buckling proves to be insufficient. Then it may be asked whether this coefficient can be improved by providing the tank with one or two stiffening circular rings fitted in the upper (thinnest) cylinder of the tank, for instance, at its lower rim and at half of its height.

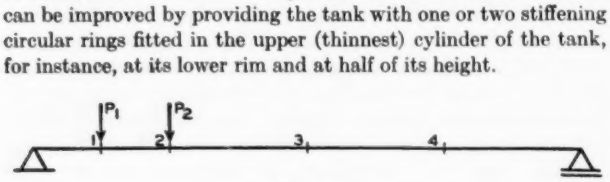

Fig. 2

It is easily seen from Fig. 2 that in our bar model such rings are translated by two external forces P_1 and P_2 at the points 1 and 2, which are proportional to the local deflections y_1 and y_2, so that

$$P_1 = -\mu_1 y_1 \text{ and } P_2 = -\mu_2 y_2 \ldots\ldots\ldots\ldots [15]$$

where μ_1 and μ_2 are essentially positive quantities. Defining inverse Maxwell numbers b_{ij} for the points 1, 2, 3, 4 as described in the preceding paragraph, and supposing y_1, y_2, y_3, y_4 to be the local deflections at the points 1, 2, 3, 4 of the deflected bar, then it is clear that the following equations hold

$$\left.\begin{aligned} P_1 = -\mu_1 y_1 &= b_{11}y_1 + b_{12}y_2 + b_{13}y_3 + b_{14}y_4 \\ P_2 = -\mu_2 y_2 &= b_{21}y_1 + b_{22}y_2 + b_{23}y_3 + b_{24}y_4 \\ 0 &= b_{31}y_1 + b_{32}y_2 + b_{33}y_3 + b_{34}y_4 \\ 0 &= b_{41}y_1 + b_{42}y_2 + b_{43}y_3 + b_{44}y_4 \end{aligned}\right\} \ldots\ldots [16]$$

having a solution (different from $y_1 = y_2 = y_3 = y_4 = 0$) only if

$$\begin{vmatrix} b_{11}+\mu_1 & b_{12} & b_{13} & b_{14} \\ b_{21} & b_{22}+\mu_2 & b_{23} & b_{24} \\ b_{31} & b_{32} & b_{33} & b_{34} \\ b_{41} & b_{42} & b_{43} & b_{44} \end{vmatrix} = 0 \ldots\ldots [17]$$

Remembering that (different from the problem treated in the sections 1 to 4, inclusive) the buckling pressure q now has a prescribed value, Equation [17] defines a relation between μ_1 and μ_2 for every set of values p and q.

If we wish that the tank be strengthened only by one ring we put μ_1 or $\mu_2 = 0$; then Equation [17] represents (for every p and q) a linear equation. If, on the other hand, we wish to strengthen it by two rings with equal coefficients of elastical support, we put $\mu_1 = \mu_2 = \mu$ and find a quadratic equation for μ, which must supply at least one positive root; only then will its solution have any practical significance for our problem. If two positive roots exist, the greater of them has to be used for the calculation of the rings. As a matter of fact Equation [17] has to be solved for a series of values of p. Every solution gives rise to a value μ_p; with every μ_p corresponds a value $I_{(p)}$ of the required moment of inertia I of the rings; the greatest of all is determinative.

Finally to derive $I_{(p)}$ from $\mu_{(p)}$ we use the well-known fact that a radial load system

$$q = q_0 \cos p\varphi \ldots\ldots\ldots\ldots [18]$$

acting on a ring produces a similar radial displacement y given by

$$y = \frac{q_0 a^4}{(p^2-1)^2 EI_{(p)}} \cos p\varphi \ldots\ldots\ldots [19]$$

From Equations [18] and [19] it follows

$$q = \frac{(p^2-1)^2 EI_{(p)}}{a^4} y \ldots\ldots\ldots\ldots [20]$$

Consequently

$$\mu_p = \frac{(p^2-1)^2 EI_{(p)}}{a^4} \quad \text{or} \quad I_p = \frac{a^4 \mu_p}{E(p^2-1)^2} \ldots\ldots [21]$$

Flow Through Granular Media

By L. P. HATCH,[1] WILSON DAM, ALA.

The author points out that the equation which appears to define flow through granular media is essentially identical to the equation for flow through pipes, but the expression is not useful to determine resistance to flow through granular media unless some of the variables are modified. The author discusses these variables and sets up formulas to determine the resistance to flow through granular media. He gives experimental results which show close agreement between calculated and observed values.

THE equation which appears to define flow through granular media is essentially identical to the equation for flow through pipes, although the flow phenomena are not similar in all respects. The equation in convenient form is

$$\frac{h}{l} = \frac{k}{g}\left(\frac{\mu}{\zeta}\right)^{2-n} U^n D^{n-3} \quad \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

where h = resistance head
l = length
k = a coefficient
g = acceleration due to gravity
μ = viscosity
ζ = density of fluid (mass per unit volume)
U = average velocity; rate of discharge per unit of cross-sectional area
D = characteristic diameter of flow channel
n = an exponent ranging in value from 1.0 for laminar flow to 2.0 for turbulent flow

In its present form Equation [1] cannot be considered a useful expression of the resistance to flow through granular media, and certain modifications in the form of some of the variables are necessary. In particular the usual concept of diameter and velocity, with respect to flow in pipes, is inadequate to represent the conditions of flow through granular media.

A brief analysis of the open structure within granular media, which forms the complex network of flow channels, will readily disclose the fact that no useful direct physical measurement of individual channels can be made, and that such measurement must be obtained from a consideration of the flow system as a whole. Furthermore, it appears evident that the measurement which characterizes the size of the flow channels will depend, largely, upon the size of the adjacent solid particles, and upon the degree to which they are packed. It is essential, therefore, that we carefully consider these factors, as well as the channel velocity, for in them lies the crux of the whole problem of flow through granular media. To permit a lucid discussion of the three important variables, certain familiar terms are introduced as follows:

α = porosity, or volume of voids divided by total or bulk volume
a = gross or bulk cross-sectional area
a_p = cross-sectional area of pores in granular media
v = average bulk velocity or rate of discharge per unit of gross or bulk cross-sectional area; this corresponds to the velocity of approach in an open portion of a tube containing granular media
v_p = average velocity within the pores or voids in the direction of generalized travel
d = representative linear dimension of solid particles
d_p = characteristic size of pores or flow channels

Velocity

In the past, critical investigations of the permeability of granular beds have, in general, brought forth identical conclusions on at least one important point, namely, the relation between void velocity v_p and the bulk or approach velocity v. The relation is given by the expression $v_p = \frac{v}{\alpha}$. Following an apparently new approach to the problem, Bakhmeteff and Feodoroff (1)[2] do not support this general opinion on the grounds that the foregoing expression is dimensionally unsound. They submit in its place the exponential form $v_p = v/\alpha^{2/3}$. This expression is derived from their relation $a_p = a\alpha^{2/3}$, which is founded upon the assumption that porosity is a volumetric parameter and that its normal exponent 1.0 must be dimensionally consistent with the rest of the equation. For a homogeneous medium, however, the ratio of open area to gross area is the same for every cross section, or

$$\alpha = \frac{a_p}{a} \times \frac{\text{length}}{\text{length}}$$

Therefore, porosity is not necessarily a volumetric parameter, and the author believes that the relation given by Bakhmeteff and Feodoroff (1) is incorrect as indicated in a discussion (2) of their paper.

Diameter of Flow Channels

At the outset, it is well recognized that the diameter of the flow channels must be some linear dimension characteristic of the flow system as a whole, with respect to size of individual channels and the resistance to flow. It appears that such a measure can be derived only in terms of the size of the adjacent particles and the degree of packing as represented, for example, by the porosity. Beyond these requirements no useful specification of the diameter is known to the author.

Numerous theories have been advanced for the derivation of a characteristic channel diameter, most of which are equally dependent upon particle size but relatively few reflect serious consideration of the all-important porosity factor.

Kozeny (3) has derived a permeability equation in which a term equivalent to the characteristic channel diameter is expressed as the surface area of particles per unit of solid volume. This, in turn, was developed from a mathematical treatment of the transverse section and marginal boundary of the unit void, together with the length of flow line. By analogy, Kozeny viewed the problem in the light of flow through tubes of uniform cross section, and he obtained an equation which, with suitable modification, has since been verified experimentally over a wide range

[1] Associate Sanitary Engineer, Tennessee Valley Authority.

Presented at the National Meeting of the Applied Mechanics Division, Ann Arbor, Mich., June 20–21, 1940, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until October 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[2] Numbers in parentheses refer to the Bibliography at the end of the paper.

of conditions. He states, moreover, that the same equation was previously developed empirically by E. Kruger (4). The equation, given for viscous flow, essentially is

$$v = C\frac{h}{l}\left(\frac{V}{A}\right)^2 \frac{\zeta}{\mu}\frac{\alpha^3}{(1-\alpha)^2} \quad [2]$$

where C = a coefficient, V = volume of particles, and A = surface area of particles.

As part of an investigation of flow through granular media at Harvard University, in which the author was associated with Gordon M. Fair, an expression for the channel diameter was derived in accordance with the concept of the hydraulic radius, a familiar term frequently employed as a size characteristic to define flow through irregular conduits. This approach appears to have paralleled the one followed previously by Kozeny, and the resulting expressions, in so far as porosity is concerned, are identical. What has previously been referred to as the Fair-Hatch expression has been discussed in other articles (5, 6), but the derivation is here reviewed as follows:

$$\text{Hydraulic radius} = \frac{\text{cross-sectional area}}{\text{wetted perimeter}} \times \frac{\text{length}}{\text{length}} =$$

$$\frac{\text{volume of voids}}{\text{surface area of solids}} = \frac{\text{volume of solids}}{\text{surface area of solids}} \times \frac{\alpha}{1-\alpha}$$

Bakhmeteff and Feodoroff (1) have introduced a diameter relationship in which porosity again is said to have suitable dimensional characteristics, i.e., $d_p = d\alpha^{1/3}$. This, also, the author believes to be incorrect on the grounds that the porosity term should take the form $\alpha/(1-\alpha)$, and, furthermore, that the foregoing expression is founded upon the characteristics of an isolated unit void rather than of the unit channel or the flow system as a whole.

Particle Size and Shape

The size of irregular particles is frequently expressed in terms of the size of opening or the "mesh" of sampling screens. The size of individual random particles retained between two screens of slightly different mesh will not be uniform but will vary in accordance with the screen openings. As is commonly true of random variations, it will be found that the measured sizes of these particles will usually follow a geometrically normal distribution. Therefore, with respect to screen sizes, there is reason to assume the geometric mean of the screen openings to most truly represent the size of the particles as a whole.

For careful analysis, however, sampling screens should not be regarded as size-measuring devices, and an independent size determination of each fraction should be made. This may be done by direct measurement of a representative number of particles and expressing the result as an average value calculated in accordance with the size distribution. Because of the multitude of "diameters" which may be used to define size of irregular particles, the results of independent investigations oftentimes are not comparable. As is frequently overlooked, the real objective in many cases is merely to obtain a representative size measure by some convenient method which will give consistent results. There is need for uniformity along these lines, and with this in mind the writer used as a measure of size the maximum projected distance between extreme edges of particles in one consistent direction; the particles lay at random in the measuring field. This method, described elsewhere, has no special merit, but it is convenient and gives consistent results. In the present study the geometric mean of individual measures within each fraction was considered a representative value.

While particle shape should be included in our concept of particle size, it appears that, at present, a separate evaluation of these two factors is necessary. In the Kozeny expression, particle shape is included in the diameter term, V/A, but for practical use this term is better represented by d/S. Here S is the shape factor and d, as before, is the representative particle diameter. Obviously, for spheres, S takes a value of 6.0, but for nonspherical particles, S becomes larger as the degree of irregularity increases. Here again, it is important that some uniform method of measuring particle diameter be adopted in order that numerical shape factors, essential to a full definition of particle size, will be directly comparable. Shape factors[3] ranging from 6.1 for well-rounded sand grains to 7.7 for angular grains were suggested by Fair and Hatch (5). The values are based upon the terminal settling velocity of the particles in water as compared with the settling rate of spheres and should be considered as approximations. Shape factors for the sands used in the present study were evaluated in the same manner, but in this case the particle shape was substantially uniform.

Uniformity of Particle Size

Except for ideal assemblages, granular media are made up of particles of unequal size. Thus, a useful general equation for flow through such material must be similarly unrestricted in its application. If the individual size portions are known, from the familiar screen analysis for example, the size characteristic of any homogeneous assemblage, conveniently represented by the area-volume ratio A/V may be calculated readily. As shown by Fair and Hatch (5), if P = weight percentage of material of uniform size d, and S = shape factor, then

$$\frac{A}{V} = \frac{S}{100}\sum\frac{P}{d} \quad [3]$$

If the assemblage is not homogeneous with respect to particle-size distribution, only one systematic arrangement of particles appears to lend itself to simplified analysis, namely, that of stratified packing. In this case the sizes increase consistently from the finest at one end to the coarsest at the other, while, with uniform particle shape and like conditions of packing, the porosity remains substantially constant. Since the resistance gradient h/l varies in accordance with the particle size, no single unit assembly is representative and the entire depth of packing L must be considered. For this purpose Fair and Hatch (5) suggest an average value of A/V, weighted with respect to flow resistance, and based upon the fact that for individual layers the percentage of total weight P is also percentage of total depth $(l/L)100$. Thus

$$\left(\frac{A}{V}\right)^2 = \frac{S^2}{100}\sum\frac{P}{d^2} \quad [4]$$

If the size distribution of random material is geometrically normal, as is frequently the case, the area-volume ratio A/V may be expressed in terms of the geometric-mean size M_g and the standard geometric deviation σ_g. Suitable equations are given by T. F. Hatch (7) which are derived from a consideration of the size distribution according to the number of particles in relation to the distribution according to weight; the latter is commonly measured by a screen analysis. In this case, for homogeneous assemblages or nonstratified beds

$$\log\frac{A}{V} = \log S - [\log M_g - 1.1513\log^2\sigma_g] \quad [5]$$

[3] Shape factors based upon particle diameters determined from size of opening of sampling screens (manufacturer's rating); these sizes differ considerably from measured diameters.

[a] Coefficient does not include value of shape S^2.

[b] Equal portions of (20–28) (28–35) (35–48) (48–60) (60–100) unstratified packing; size calulated from $\frac{1}{100}\sum\frac{P}{d}$.

[c] Equal portions of (20–28) (35–48) (48–60) stratified packing; size calculated from $\left[\frac{1}{100}\sum\frac{P}{d^3}\right]^{1/3}$.

[d] Equal portions of (20–28) (35–48) (48–60) unstratified packing.

while for stratified beds

$$\log \left(\frac{A}{V}\right)^2 = \log S^2 - [\log M_g^2 - 4.6052 \log^2 \sigma_g] \ldots . [6]$$

Area-Volume Ratio

So far as the author is aware, no satisfactory useful method of determining surface area of irregularly shaped particles has yet been presented. Attempts have been made to correlate surface area with solution rate, and with coating films of molecular thickness, but the procedures are involved and yield results which apparently are subject to gross error.

For particles somewhat symmetrical in outline, however, it would seem that an approximately uniform relationship may exist between the area-volume ratio of the particles and their terminal settling rates in suitable fluids. Certain factors may enter into such a relationship which do not yield to simplified analysis but, for practical purposes, it is conceivable that they would play a minor role within a desired range of motion.

In the present study, each size fraction of sand was made up of grains having practically uniform shape characteristics, in which case the area-volume ratio for each size would be expected to bear a substantially constant relation to a representative particle diameter. Hence, the numerical effect of shape is absorbed in the equation coefficient.

The Generalized Equation

Evaluation of the channel velocity and the channel diameter, including also the particle-size distribution factor, permits a restatement of Equation [1], possibly extending its useful application to the general problem of flow through granular media. Thus

$$\frac{h}{l} = \frac{k}{g}\left(\frac{\mu}{\zeta}\right)^{2-n} \left(\frac{v}{\alpha}\right)^n \left(\frac{A}{V}\,\frac{1-\alpha}{\alpha}\right)^{3-n} \ldots\ldots\ldots [7]$$

Experimental Procedure

There are a number of practical considerations, oftentimes overlooked, with respect to the measurement of flow through granular media, which influence the accuracy of the results. Some of these are as follows: (*a*) The apparatus should be designed for simplicity of operation and to permit close observation of the conditions of packing and flow; (*b*) the packing should follow some specified orderly arrangement; (*c*) all disturbing factors, particularly trapped air bubbles with liquid flow, should be eliminated; (*d*) static equilibrium of pressures must be reached before resistances are recorded; (*e*) substantially constant temperatures must be maintained.

In the present study the medium (sand) was packed in a glass tube about 2 in. in diameter and 5 ft long, having suitable side taps for maintaining a constant liquid level above the medium and permitting a measurement of static pressures. The tube was supported vertically to facilitate the uniform packing of particles and to simplify the measurement of resistance. With the glass tube irregularities in the packing and other disturbing factors could be readily detected.

With uniform, and vertically stratified nonuniform media, the individual particles were first suspended in an upward-flowing stream of distilled water until all air bubbles were removed. The particles were then allowed to settle into place gradually and the direction of flow reversed; deaerated distilled water was used in all tests.

With unstratified nonuniform media, on the other hand, the foregoing procedure obviously could not be used, but good results were obtained by first evacuating the voids in a dry medium and then allowing the deaerated water to enter slowly from the bottom. It was necessary to adjust the rate of flow carefully in order to prevent air from being further released from solution, and also to secure the medium in place while the water was rising.

Experimental Results

To simplify the experimental considerations, Equation [7] may be rearranged in the form

$$\frac{h}{l} = \frac{k}{g}\left(\frac{\mu}{\zeta}\right)^{2-n} v^n \left(\frac{A}{V}\right)^{3-n} \left(\frac{(1-\alpha)^{3-n}}{\alpha^3}\right) \ldots\ldots [8]$$

Briefly, the author's tests covered a range of viscous flow ($n = 1$) of water through sands of similar particle shape, but differing considerably in particle size and size distribution. The last three factors in Equation [8] were investigated in their separate influence upon the resistance gradient and good agreement with the theoretical relationship was found in each case. To bring about a variation of porosity within a single test, each individual sand was placed in the tube with relatively loose packing, and with each successive test run the medium was consolidated by tapping the tube uniformly on the outside.

To simplify the analysis of the data with respect to Equation [8], the combined influence of all variables (except shape factors which were assumed to be constant) is reflected in the value of the coefficient k given in Table 1. The approximate constancy of the coefficient appears to verify the general correctness of Equation [8].

Carman (8), in a study of specific surface of particles, gives extensive experimental data to verify the Kozeny porosity factor in Equation [8], covering a range of porosities of 0.485 to 0.855. The corresponding change in the value of $(1 - \alpha)^2/\alpha^3$ is from 2.32 to 0.034, and the deviation between calculated and observed values is said to be ±5 per cent. The author has never been able to demonstrate such close agreement between theory and experiment, probably for reasons outlined as follows: (*a*) Difficulties of determining accurately the particle size and shape; (*b*) irregularities in packing, especially when mixed sizes were used; (*c*) experimental errors which, even with careful technique, appeared to be unavoidable. For normally accurate work over a substantial range of particle assemblage, the margin of error may well exceed ±10 per cent.

Effects of a Change of Poisson's Ratio Analyzed by Twinned Gradients

Illustrated by Simple Solutions of Boussinesq's Problem of a Normal Force and Cerruti's Problem of a Tangential Force Acting on the Surface of a Large Solid, and by a Simple Derivation of the Stresses in a Rotating Thick Disk

By H. M. WESTERGAARD,[1] CAMBRIDGE, MASS.

Some problems of elasticity have a simple solution for a particular value of Poisson's ratio. For example, Boussinesq's problem of a normal force and Cerruti's problem of a tangential force, acting on the plane surface of a semi-infinite solid, are solved when Poisson's ratio is $^1/_2$ by referring to Kelvin's problem of a force at a point in the interior of an infinite solid. For, when Poisson's ratio is $^1/_2$, the solution of Kelvin's problem can be stated in terms of one principal stress at each point, acting along the radial line from the point of the load; the other principal stresses are zero; and one half of the total force may be assigned to one half of the infinite solid. For other values of Poisson's ratio terms must be added in the formulas for the displacements and stresses.[2, 3, 4, 5, 6] The derivations that have been available are somewhat lengthy, especially for Cerruti's problem. The difficulties are reduced by a simple analytical device, here called "the twinned gradient." The displacement to be added by the change of Poisson's ratio is stated as the gradient of a potential except that one of the components is replaced by its twin, an identical component in reversed direction. This device also lends itself to a simplification of the analysis of stresses in a rotating thick disk.[7]

Notation

x, y, z = rectangular coordinates
r, θ, z = cylindrical coordinates
R = length of radius vector from the origin to the point x, y, z
$\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{k}$ = unit vectors in the directions of x, y, and z
$\boldsymbol{\rho}$ = displacement as a vector
ξ, η, ζ = components of $\boldsymbol{\rho}$ in the directions of x, y, and z
$\operatorname{div} \boldsymbol{\rho} = \dfrac{\partial \xi}{\partial x} + \dfrac{\partial \eta}{\partial y} + \dfrac{\partial \zeta}{\partial z}$ = divergence of $\boldsymbol{\rho}$ = increase of volume per unit of volume
$\nabla = \boldsymbol{i}\dfrac{\partial}{\partial x} + \boldsymbol{j}\dfrac{\partial}{\partial y} + \boldsymbol{k}\dfrac{\partial}{\partial z}$ = the operator nabla
$\Delta = \dfrac{\partial^2}{\partial x^2} + \dfrac{\partial^2}{\partial y^2} + \dfrac{\partial^2}{\partial z^2}$ = Laplace's operator
$\sigma_x, \sigma_y, \sigma_z$ = normal stresses in the directions of x, y, and z, positive in tension
$\tau_{xy}, \tau_{yz}, \tau_{zx}$ = shearing stresses in the directions of x, y, and z
$\sigma_r, \sigma_\theta, \sigma_z, \tau_{r\theta}, \tau_{\theta z}, \tau_{zr}$ = corresponding stresses in the directions of the cylindrical coordinates
$\Theta = \sigma_x + \sigma_y + \sigma_z = \sigma_r + \sigma_\theta + \sigma_z$ = bulk stress
G = modulus of elasticity in shear
m, μ = values of Poisson's ratio
$\boldsymbol{K}$ = body force per unit of volume, a vector

The Twinned Gradient

Assume that a set of displacements

$$\boldsymbol{\rho}' = \boldsymbol{i}\xi' + \boldsymbol{j}\eta' + \boldsymbol{k}\zeta' \quad \ldots\ldots\ldots\ldots\ldots [1]$$

and stresses σ', τ' have been found to apply when Poisson's ratio has the particular value m and when the body forces per unit of volume are $\boldsymbol{K}'$. Then $\boldsymbol{\rho}'$ is a vector function satisfying the equation of elasticity

$$G\left(\Delta + \frac{1}{1-2m}\nabla \operatorname{div}\right)\boldsymbol{\rho}' + \boldsymbol{K}' = 0 \quad \ldots\ldots [2]$$

The corresponding stresses are defined by equations of the form

$$\sigma_x' = 2G\left(\frac{\partial \xi'}{\partial x} + \frac{m}{1-2m}\operatorname{div}\boldsymbol{\rho}'\right) \quad \ldots\ldots [3]$$

$$\tau_{xy}' = G\left(\frac{\partial \xi'}{\partial y} + \frac{\partial \eta'}{\partial x}\right) \quad \ldots\ldots\ldots\ldots [4]$$

$$\Theta' = \sigma_x' + \sigma_y' + \sigma_z' = \frac{2(1+m)G}{1-2m}\operatorname{div}\boldsymbol{\rho}' \quad \ldots\ldots [5]$$

Assume now that Poisson's ratio is changed from m to μ, while the modulus of elasticity in shear G remains unchanged. Assume for the time being that the displacements $\boldsymbol{\rho}'$ are held unchanged. The new set of body forces required by these assumptions need not be expressed. The shearing stresses, according to Equation [4], will remain unchanged. The normal stresses, according to Equation [3], will increase in all directions by the amount

Presented at the National Meeting of the Applied Mechanics Division, Ann Arbor, Mich., June 20–21, 1940, of The American Society of Mechanical Engineers.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until October 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

$$\bar{\sigma} = 2G\left[\frac{\mu}{1-2\mu} - \frac{m}{1-2m}\right]\operatorname{div}\boldsymbol{\rho}' = \frac{2(\mu-m)G}{(1-2\mu)(1-2m)}\operatorname{div}\boldsymbol{\rho}' \quad [6]$$

which may be restated by use of Equation [5] as

$$\bar{\sigma} = \frac{\mu-m}{(1+m)(1-2\mu)}\Theta' \quad [7]$$

The change is completed by adding the displacements $\boldsymbol{\rho}''$ to $\boldsymbol{\rho}'$, thereby creating the final displacements

$$\boldsymbol{\rho} = \boldsymbol{\rho}' + \boldsymbol{\rho}'' \quad [8]$$

and the final stresses

$$\sigma = \sigma' + \sigma'', \qquad \tau = \tau' + \tau'' \quad [9]$$

which require the final body forces

$$\boldsymbol{K} = \boldsymbol{K}' + \boldsymbol{K}'' \quad [10]$$

The choice is made to investigate the possibility of expressing $\boldsymbol{\rho}''$ by a twinned gradient, defined by reversal of sign of the z-component of the gradient $-\nabla\varphi$ of a function $-\varphi$. The proposed formula is

$$2G\boldsymbol{\rho}'' = -\boldsymbol{i}\frac{\partial\varphi}{\partial x} - \boldsymbol{j}\frac{\partial\varphi}{\partial y} + \boldsymbol{k}\frac{\partial\varphi}{\partial z} = -\nabla\varphi + \boldsymbol{k}\cdot 2\frac{\partial\varphi}{\partial z} \quad [11]$$

By referring to Equation [4] it is seen that

$$\tau_{zz}'' = \tau_{zy}'' = 0, \quad \tau_{xy}'' = -\frac{\partial^2\varphi}{\partial x\,\partial y} \quad [12]$$

Also

$$2G\operatorname{div}\boldsymbol{\rho}'' = -\frac{\partial^2\varphi}{\partial x^2} - \frac{\partial^2\varphi}{\partial y^2} + \frac{\partial^2\varphi}{\partial z^2} = -\Delta\varphi + 2\frac{\partial^2\varphi}{\partial z^2} \quad [13]$$

By referring to Equation [3] and noting that the normal stresses were previously increased by $\bar{\sigma}$ one finds

$$\sigma_z'' = \bar{\sigma} + 2G\left(\frac{\partial\zeta''}{\partial z} + \frac{\mu}{1-2\mu}\operatorname{div}\boldsymbol{\rho}''\right) \quad [14]$$

or, by Equations [7] and [13]

$$\sigma_z'' = \frac{\mu-m}{(1+m)(1-2\mu)}\Theta' + \frac{1}{1-2\mu}\left(\frac{\partial^2\varphi}{\partial z^2} - \mu\Delta\varphi\right) \quad [15]$$

The further choice is made to impose the requirement

$$\sigma_z'' = 0 \quad [16]$$

This requirement is satisfied when

$$\frac{\partial^2\varphi}{\partial z^2} - \mu\Delta\varphi = \frac{m-\mu}{1+m}\Theta' \quad [17]$$

Equations [3] and [16] permit a computation of σ_x'':

$$\sigma_x'' = \sigma_x'' - \sigma_z'' = 2G\left(\frac{\partial\xi''}{\partial x} - \frac{\partial\zeta''}{\partial z}\right) = -\frac{\partial^2\varphi}{\partial x^2} - \frac{\partial^2\varphi}{\partial z^2} = \frac{\partial^2\varphi}{\partial y^2} - \Delta\varphi \quad [18]$$

The complete set of stresses produced by the changes may now be recorded:

$$\sigma_z'' = \tau_{zx}'' = \tau_{zy}'' = 0 \quad [19]$$

$$\left.\begin{aligned}\sigma_x'' &= \frac{\partial^2\varphi}{\partial y^2} - \Delta\varphi\\ \sigma_y'' &= \frac{\partial^2\varphi}{\partial x^2} - \Delta\varphi\\ \tau_{xy}'' &= -\frac{\partial^2\varphi}{\partial x\,\partial y}\end{aligned}\right\} \quad [20]$$

It remains to express the body forces that are required to maintain the stresses in Equation [20]. By use of the two equations of equilibrium of the form

$$\frac{\partial\sigma_x''}{\partial x} + \frac{\partial\tau_{xy}''}{\partial y} + K_x'' = 0 \quad [21]$$

one finds

$$\boldsymbol{K}'' = \boldsymbol{i}\frac{\partial\Delta\varphi}{\partial x} + \boldsymbol{j}\frac{\partial\Delta\varphi}{\partial y} \quad [22]$$

The function φ must satisfy Equations [17] and [22].

In the majority of significant cases both the original and the final body forces are zero. That is,

$$\boldsymbol{K}' = \boldsymbol{K}'' = \boldsymbol{K} = 0 \quad [23]$$

Then Equation [22] is satisfied if

$$\Delta\varphi = 0 \quad [24]$$

that is, if φ is a harmonic function. Equation [17] is satisfied if in addition

$$\frac{\partial^2\varphi}{\partial z^2} = \frac{m-\mu}{1+m}\Theta' \quad [25]$$

It is possible to satisfy Equations [24] and [25] at the same time because $\Delta\Theta' = 0$; Θ' is a harmonic function. With $\Delta\varphi$ removed in Equations [20], φ becomes an Airy function for the stresses in the directions of x and y.

Some of the equations that have been stated become indefinite when $m = 1/2$; but considerations of convergence show that the remaining equations remain applicable in this limiting case. This conclusion is reached also by a direct study of the limiting case of $m = 1/2$.

Statement of the Solution of Kelvin's, Boussinesq's, and Cerruti's Problems When Poisson's Ratio Is 1/2

In Kelvin's problem a solid is considered which extends infinitely far in all directions. At the origin of the coordinates a concentrated force $2P$ is applied in the direction of z, which is assumed to be vertical downward. In Boussinesq's problem the semi-infinite solid $z \geqq 0$ is considered; the concentrated normal pressure P acts at the origin of the coordinates in the direction of z. In Cerruti's problem, for the time being the semi-infinite solid $y \geqq 0$ is considered, with the tangential force P acting at the origin of the coordinates in the direction of z.

When Poisson's ratio is 1/2,

$$m = 1/2 \quad [26]$$

the solution of all three problems can be stated by the same formulas. In doing so it is expedient to use, besides the rectangular coordinates x, y, z, also the cylindrical coordinates r, θ, z, and the polar coordinate R; r and R being defined by the equations

$$R^2 = r^2 + z^2 = x^2 + y^2 + z^2 \quad [27]$$

The formulas follow:

Displacement in the direction of the horizontal radial coordinate r:

$$\rho_r' = \frac{P}{4\pi G}\frac{rz}{R^3} \quad \ldots\ldots [28]$$

Resultant displacement:

$$\boldsymbol{\rho}' = \frac{P}{4\pi GR^3}\left[\boldsymbol{i}xz + \boldsymbol{j}yz + \boldsymbol{k}(R^2 + z^2)\right] \quad \ldots\ldots [29]$$

Principal stress, in the direction of the radius vector R, equal to the bulk stress Θ', the other two principal stresses being zero:

$$\sigma_R' = \Theta' = -\frac{3P}{2\pi}\frac{z}{R^3} \quad \ldots\ldots [30]$$

Corresponding components of stress:

$$\sigma_r' = -\frac{3P}{2\pi}\frac{r^2z}{R^5}, \quad \sigma_\theta' = 0, \quad \sigma_z' = -\frac{3P}{2\pi}\frac{z^3}{R^5} \quad \ldots [31]$$

$$\tau_{r\theta}' = 0, \quad \tau_{\theta z}' = 0, \quad \tau_{rz}' = -\frac{3P}{2\pi}\frac{rz^2}{R^5} \quad \ldots\ldots [32]$$

$$\left.\begin{aligned}\sigma_x' &= -\frac{3P}{2\pi}\frac{x^2z}{R^5}\\ \sigma_y' &= -\frac{3P}{2\pi}\frac{y^2z}{R^5}\\ \sigma_z' &= -\frac{3P}{2\pi}\frac{z^3}{R^5}\end{aligned}\right\} \quad \ldots\ldots [33]$$

$$\left.\begin{aligned}\tau_{xy}' &= -\frac{3P}{2\pi}\frac{xyz}{R^5}\\ \tau_{yz}' &= -\frac{3P}{2\pi}\frac{yz^2}{R^5}\\ \tau_{zx}' &= -\frac{3P}{2\pi}\frac{xz^2}{R^5}\end{aligned}\right\} \quad \ldots\ldots [34]$$

BOUSSINESQ'S PROBLEM FOR ANY VALUE OF POISSON'S RATIO

With $m = 1/2$ and Θ' as in Equation [30], Equation [25] gives

$$\frac{\partial^2\varphi}{\partial z^2} = \frac{1-2\mu}{3}\Theta' = -\frac{(1-2\mu)P}{2\pi}\frac{z}{R^3} \quad \ldots\ldots [35]$$

$$\frac{\partial\varphi}{\partial z} = \frac{(1-2\mu)P}{2\pi R}, \quad \varphi = \frac{(1-2\mu)P}{2\pi}\log(R+z) \quad \ldots [36]$$

This φ is a harmonic function. By referring to Equation [11] one finds the displacements to be added to those in Equations [28] and [29]:

$$\left.\begin{aligned}\rho_r'' &= -\frac{1}{2G}\frac{\partial\varphi}{\partial r} = -\frac{(1-2\mu)P}{4\pi G}\frac{r}{R(R+z)}\\ \zeta'' &= \frac{1}{2G}\frac{\partial\varphi}{\partial z} = \frac{(1-2\mu)P}{4\pi GR}\end{aligned}\right\} \quad \ldots [37]$$

By referring to Equations [20] and [24], one finds the two and only two stresses that will be superposed on those in Equations [31] and [32]:

$$\sigma_r'' = \frac{1}{r}\frac{\partial\varphi}{\partial r} = \frac{(1-2\mu)P}{2\pi}\frac{1}{R(R+z)} \quad \ldots\ldots [38]$$

$$\sigma_\theta'' = \frac{\partial^2\varphi}{\partial r^2} = -\frac{1}{r}\frac{\partial\varphi}{\partial r} - \frac{\partial^2\varphi}{\partial z^2}$$

$$= \frac{(1-2\mu)P}{2\pi}\left(-\frac{1}{R(R+z)} + \frac{z}{R^3}\right) \quad \ldots\ldots [39]$$

CERRUTI'S PROBLEM

In dealing with Cerruti's problem it is expedient now to change the directions so that the force P at the origin of coordinates will act in the direction of x on the semi-infinite solid $z \geq 0$. Accordingly, Equations [27] to [34] are reinterpreted with changes of x to y, y to z, z to x, $\boldsymbol{i}$ to $\boldsymbol{j}$, $\boldsymbol{j}$ to $\boldsymbol{k}$, and $\boldsymbol{k}$ to $\boldsymbol{i}$.

Then Equations [25] and [30] give

$$\frac{\partial^2\varphi}{\partial z^2} = \frac{1-2\mu}{3}\Theta' = -\frac{(1-2\mu)P}{2\pi}\frac{x}{R^3} \quad \ldots\ldots [40]$$

By two integrations one finds the two successive harmonic functions

$$\frac{\partial\varphi}{\partial z} = \frac{(1-2\mu)P}{2\pi}\frac{x}{R(R+z)}, \quad \varphi = -\frac{(1-2\mu)P}{2\pi}\frac{x}{R+z} \quad \ldots [41]$$

By substituting this function φ in Equations [11] and [20] and adding the values to those derived from Equations [29], [33], and [34] by changing directions, one obtains the following formulas, which are the solution of the problem:

$$\xi = \frac{P}{4\pi GR}\left[1 + \frac{x^2}{R^2} + (1-2\mu)\left(\frac{R}{R+z} - \frac{x^2}{(R+z)^2}\right)\right] \quad \ldots [42]$$

$$\eta = \frac{P}{4\pi GR}\left[\frac{xy}{R^2} - \frac{(1-2\mu)xy}{(R+z)^2}\right] \quad \ldots\ldots [43]$$

$$\zeta = \frac{P}{4\pi GR}\left[\frac{xz}{R^2} + \frac{(1-2\mu)x}{R+z}\right] \quad \ldots\ldots [44]$$

$$\sigma_x = \frac{Px}{2\pi R^3}\left[-\frac{3x^2}{R^2} + \frac{1-2\mu}{(R+z)^2}\left(R^2 - y^2 - \frac{2Ry^2}{R+z}\right)\right] \quad \ldots [45]$$

$$\sigma_y = \frac{Px}{2\pi R^3}\left[-\frac{3y^2}{R^2} + \frac{1-2\mu}{(R+z)^2}\left(3R^2 - x^2 - \frac{2Rx^2}{R+z}\right)\right] \quad \ldots [46]$$

$$\sigma_z = -\frac{3Pxz^2}{2\pi R^5}, \quad \Theta = -\frac{(1+\mu)Px}{\pi R^3} \quad \ldots\ldots [47]$$

$$\tau_{xy} = \frac{Py}{2\pi R^3}\left[-\frac{3x^2}{R^2} + \frac{1-2\mu}{(R+z)^2}\left(-R^2 + x^2 + \frac{2Rx^2}{R+z}\right)\right] \quad \ldots\ldots [48]$$

$$\tau_{yz} = -\frac{3Pxyz}{2\pi R^5}, \quad \tau_{zx} = -\frac{3Px^2z}{2\pi R^5} \quad \ldots\ldots [49]$$

ROTATING THICK DISK

It is desired to determine the stresses in a disk, with the sides $z = \pm c$ and the edge $r = a$, rotating about the axis of z with a constant angular velocity ω. The body force is the centrifugal force per unit of volume, $w\omega^2 r/g$, in which w/g is the mass per unit of volume. Timoshenko[3] has shown a solution of this problem. The method of the twinned gradient permits a simple derivation.

In the initial state the body forces and the stresses are taken as zero. Then φ may be assumed to account for the total body force and stresses, except that a simple state of stress may be superposed at the end of the computations. Accordingly

$$K = K'', \quad \sigma = \sigma'', \quad \text{and} \quad \tau = \tau'' \quad \ldots\ldots [50]$$

Then Equations [17] and [22] will be satisfied if

[3] Compare S. Timoshenko, loc. cit., pp. 319–320.

$$\frac{\partial^2 \varphi}{\partial z^2} = \mu \Delta\varphi \quad \text{and} \quad \Delta\varphi = \frac{w\omega^2}{2g}(r^2 + f(z)) \ldots\ldots [51]$$

The polynomial

$$\varphi = (w\omega^2/g)(Ar^4 + Br^2z^2 + Cz^4) \ldots\ldots [52]$$

is chosen for investigation. Substitution from Equation [52] in Equations [51] gives three linear equations for the constants A, B, and C. Thereby one finds

$$\varphi = \frac{w\omega^2}{g}\left(\frac{1-\mu}{32} r^4 + \frac{\mu}{4} r^2z^2 + \frac{\mu^2}{12(1-\mu)} z^4\right) \ldots\ldots [53]$$

and

$$\Delta\varphi = \frac{w\omega^2}{g}\left(\tfrac{1}{2} r^2 + \frac{\mu}{1-\mu} z^2\right) \ldots\ldots [54]$$

which satisfy Equations [51].

The two stresses that do not vanish may now be written in accordance with Equations [20], but with a constant tension σ_0 superposed to make the load on the edge vanish as nearly as possible:

$$\sigma_r = \frac{1}{r}\frac{\partial \varphi}{\partial r} - \Delta\varphi + \sigma_0$$

$$= \frac{w\omega^2}{g}\left[\frac{3+\mu}{8}(a^2 - r^2) + \frac{\mu(1+\mu)}{6(1-\mu)}(c^2 - 3z^2)\right] \ldots\ldots [55]$$

$$\sigma_\theta = \frac{\partial^2 \varphi}{\partial r^2} - \Delta\varphi + \sigma_0$$

$$= \frac{w\omega^2}{g}\left[\frac{3+\mu}{8} a^2 - \frac{1+3\mu}{8} r^2 + \frac{\mu(1+\mu)}{6(1-\mu)}(c^2 - 3z^2)\right] \ldots [56]$$

which are the values given by Timoshenko. When c is not too great, the radial stresses which remain at the edge according to Equation [55] constitute a load that balances itself locally. Its removal, by superposing an equal and opposite load, would cause only local effects near the edge.

Torsional Vibration in Geared-Turbine Propulsion Equipment

By H. PORITSKY,[1] SCHENECTADY, N. Y., AND C. S. L. ROBINSON,[2] LYNN, MASS.

Two alternative methods are presented by the authors for the determination of torques in the propelling machinery of ships when friction is taken into account. One is called the "direct method," while the other is called the "method of normal coordinates." The latter is described at length, showing the great saving of numerical work possible by its use when compared to the direct method.

The paper points out that at critical propeller speeds oscillatory torques are limited only by damping. Two types of damping are taken into account: One is damping of the propeller in water; the other is friction in the driving mechanism, introduced as solid friction in the shafts similar to damping in the metal.

IN THE propelling machinery of ships, several modes of torsional vibration may occur at certain critical speeds within the running range. If the amplitudes of these vibrational torques become greater than the respective driving torques in any one of the shafts, chattering of the gear teeth or lifting of the journal affected might result.

The critical frequencies are determined by the inertias, stiffnesses, and gear ratios of the propulsion equipment. The exciting stimulus for the torsional vibrations is provided largely by the blades of the propeller as they approach and recede from the hull or sternpost of the boat. At critical speeds the oscillatory torques are limited only by damping. Two types of damping are taken into account: One is damping of the propeller in water; the other is friction in the driving mechanism, introduced as solid friction in the shafts similar to damping in the metal.

Two alternative methods are presented herein for the determination of torques when friction is taken into account. One of them is referred to as the "direct method" and is explained in section 7. The other one is called the "Method of Normal Coordinates;" it is described at length in sections 8 and 9 and is summarized in section 10. While the method of normal coordinates appears at first sight unduly long and involved, the fact remains that this method, once mastered, will result in a great saving of numerical work as compared with the direct method.

A schematic diagram of the propulsion drive considered is shown in Fig. 1. Most of the discussion applies to other arrangements as well.

An equivalent system, to which the one shown in Fig. 1 is reduced, is shown in Fig. 2.

1—Nomenclature

The nomenclature used in the paper is as follows:

n = number of propeller blades

N = propeller speed, rpm

$\omega_p = N2\pi/60 = 0.1047\,N$ = propeller speed, radians per sec

f = excitation frequency, cycles per sec $= Nn/60$

$\omega = n\omega_p$ = excitation frequency, radians per sec

$I_p, I_1, \ldots = WR^2/g$ lb-in. sec^2 = moment of inertia in mass rather than weight units

$K_0, K_1, \ldots$ = stiffness constants of various shafts, in-lb per radian

$\theta_p, \theta_0, \ldots$ = angular displacement of various inertias or the amplitude[3] of such displacements, radians

$T_0, T_1, \ldots$ = torque in shaft $K_0, K_1 \ldots$, in-lb per radian or the amplitude of this torque

T_e = exciting torque applied at the propeller, or its amplitude, in-lb per radian

φ = solid-friction damping factor = fraction of maximum elastic energy dissipated per amplitude cycle

$\epsilon = \varphi/2\pi$

D = damping constant for a shaft, in-lb sec

D_p = damping constant for propeller, in-lb sec

$C = D_p/\omega$. The introduction of C leads to algebraic simplification

$\omega_0, \omega_1, \ldots \omega_s$ = critical frequencies, in rad per sec; $\omega_0 = 0$ corresponds to the "degenerate" critical frequency $\omega = 0$; ω_1 corresponds to the first true critical frequency, etc.

E = kinetic energy of system

V = potential energy of system

Referring to the normal coordinates in sections 8 and 9:

q_i = normal coordinate of any displacement of system. The coordinate q_i specifies the amount of the ith critical shape of vibration present in an actual displacement. Its dimensions are the same as those of θ.

A_i = constant factor having the dimensions of stiffness constants K, in-lb per radian

B_i = constant factor having the dimensions of inertia constants I, in-lb sec^2

Q_i = "generalized force" defined by the equation: $Q_i dq_i$ = work done in displacement dq_i by the forces or torques whose effect is not included in V

The I's, K's, θ's, T's are for the equivalent system, possessing no gears as discussed in section 2, and the θ's, T's, V, E are reckoned relative to a steady state determined by the average load and speed.

2—Inertia and Stiffness Constants

The calculation of the natural frequencies does not depend on the magnitude of the exciting torque and on the damping but only on the inertia and stiffness constants.

It is convenient to use an "equivalent system" as shown in Fig. 2, which has no gears (or has gears that effect no change of speed) and whose natural frequencies are the same as the frequencies of the original system. This is possible, because, while the double-reduction gears in turn effect a change of rotary speed of ratio R_1:1, R_2:1, it will be noted that an oscillatory vibration will be transmitted through the gears without change of frequency

Presented at the National Meeting of the Applied Mechanics Division, New York, N. Y., June 14–15, 1939, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until October 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[3] In the sense used here the quantity $A \cos(\omega t + \varphi)$ possesses the amplitude A and not $2A$.

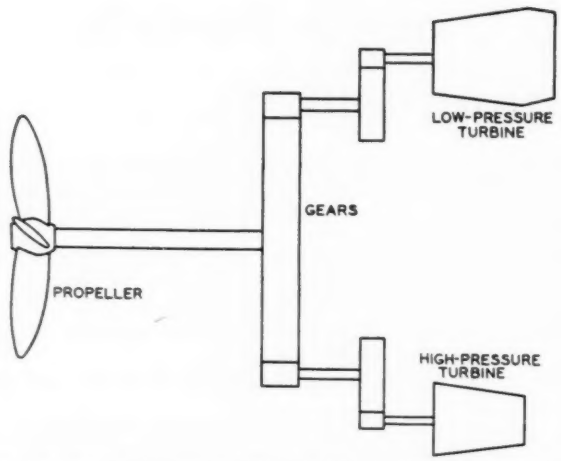

FIG. 1 ARRANGEMENT OF A TYPICAL MARINE-PROPULSION UNIT

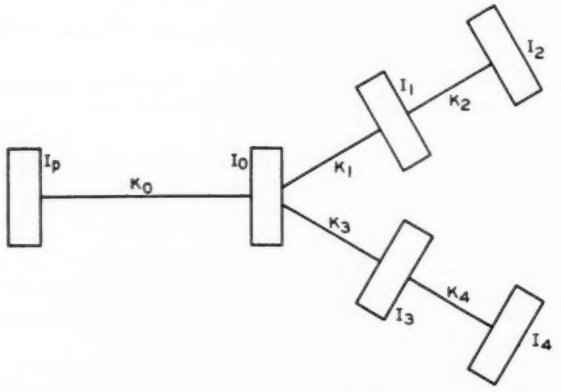

FIG. 2 AN ARRANGEMENT OF A MARINE-PROPULSION UNIT WHICH IS EQUIVALENT TO THE ONE SHOWN IN FIG. 1

but with a proper change of amplitude. The inertias and stiffnesses for the equivalent inertia are obtained as follows.

Starting at the propeller end, I_p and K_0, shown in Fig. 2, are taken equal to the moment of inertia of the propeller and the stiffness of the propeller shaft shown in Fig. 1. Progressing away from the propeller, after one passes through a gear of step-up ratio R:1, the actual I's and K's occurring beyond are multiplied by R^2. If several gears are passed, then the subsequent I's and K's are multiplied by the squares of the step-up ratios of each gear. Thus the inertia I_0 for Fig. 2 is obtained by adding to the moment of inertia of the big gear the moments of inertia of the two pinions multiplied by R_1^2, while I_2, K_2 for Fig. 2 are obtained by multiplying $R_1^2R_2^2$ the I_2, K_2 of Fig. 1. It may be shown that an equivalent system so obtained has the same natural frequencies as the actual system, as well as the same position of nodes (whether in free or forced oscillation). The amplitudes and torques of the two systems are also definitely related, as shown by

$$\text{Multiply the actual } \begin{Bmatrix} I \\ K \\ T \\ \theta \end{Bmatrix} \text{ by } \begin{Bmatrix} R^2 \\ R^2 \\ R \\ 1/R \end{Bmatrix} \text{ to obtain the equivalent value}$$

As explained previously, the step-up ratios R used here are those of the gears encountered in passing from the propeller to the shaft or inertia under consideration.

If we suppose that the equivalent system with gears of speed ratio 1:1 is used to deliver power to the propeller and that the generation of power is properly divided between the two branches, it will be seen that the steady and oscillatory torques are changed in the same ratio in each branch. Thus the equivalent system can be used directly to examine questions of chattering at the gears.

The calculation of inertias and stiffnesses of each member of the drive can be made with good accuracy from the blueprints. The following items must be kept in mind:

1 The inertia of the propeller is increased to allow for entrained water. By various tests, the increase of inertia is estimated to be around 25 per cent of the inertia of the propeller. One authority mentions 23 to 32 per cent (1).[4] The higher figure applies when the propeller blades have broad tips. The shipbuilder commonly supplies a figure for this increase in inertia.

2 The moment of inertia of the shaft which joins two large members is assumed to be divided equally between the two larger inertias. This is not strictly correct. It may be shown that if a node exists at one end of the shaft, then it is fairly correct to add a third of its moment of inertia to the inertia of the member at the other end. If a node exists in the middle, then a third of the inertia of the portion of the shaft to each side of the node should be added onto the respective inertia of the member at that end. Since the position of the node cannot be calculated beforehand, this procedure is not recommended and the straightforward addition of half of the inertia to the members on each side has been adopted. However, it must be added that the effect of the inertia of the shaft is generally quite small.

3 Gear and pinion teeth are assumed to be rigid. This is confirmed by estimates of gear-teeth deflections converted into angular displacements. It is also true of coupling teeth.

3—EXCITATION FACTORS

There is a once-per-revolution excitation due to unbalance or misalignment in any rotating part. The frequency of this may be N (the propeller frequency) or NR_1, or NR_1R_2 (the turbine rotation frequency). However, in every case it tends to produce a *transverse* vibration and cannot be considered as a cause of torsional oscillations.

Defects of gears may serve as a cause of high-frequency torsional oscillations, though with a double-helical type and the high perfection of present gear cutting, this effect is negligible.

Asymmetry of the propeller blades may cause a torsional stimulus of once-per-revolution frequency. The chief cause of torsional vibration, however, lies in the variation of the torque on the propeller due to the variation of the water forces on the blades during their rotation. The frequency of this variation is the blade frequency, that is, the propeller frequency multiplied by the number of blades.

The cause of such torque irregularities is known as circumferential wake variation (2). A partial list of factors which may make the hydrodynamic field around the propeller nonuniform is as follows:

1 The sternpost and the rudder. This is important in single-screw ships, where, with an even number of propeller blades, the effect is doubled. Hence single-screw ships tend to have large torsional excitation factors.

2 The distortion of the hydrodynamic field near the hull. This is an important factor in ships with two or four screws. As each blade tip passes near the hull there is a torque impulse.

3 The propeller operating near or at the surface of the water. This may be very important in the case of a ship lightly loaded. Also it often accounts for the accentuation of the vibration in rough water.

[4] The numbers in parentheses refer to the Bibliography at the end of the paper.

4 Protuberances in the ship's hull, such as propeller shaft bossings.

The amplitude of this exciting torque is generally given as a fraction of the propelling torque. This is possible because the wake around the propeller remains similar at all operating speeds.

One of the first articles on the subject is by A. T. Thorne and J. Calderwood (3). They measured the variation in the propeller resisting torque in a number of ships and, allowing for resonance effects, found that the excitation factor was not likely to exceed 10 per cent for smooth water. A complete study of a twin-screw steamer, the *President Hoover*, was made by F. M. Lewis (4). He found from a careful analysis of model experiments an excitation factor of 3.2 per cent and torsiograph records taken on the actual ship showed 3.3 per cent.

From the foregoing discussion it would seem that a conservative figure for the case where there is more than one screw is 7.5 per cent. A figure as low as $3^1/_2$ per cent has been recommended in some cases; this is based on measurements.

There are also some indirect references to blade frequency excitation. J. L. Kent (5) has mentioned it as being noticeable in one particular case when the stern was rising. J. H. Gibson, in commenting on an article by H. E. Saunders (6), speaks of blade pulsations in the propeller thrust.

It is to be kept in mind that the driving power which is transmitted through the propeller as a torque reacts on the water largely as a thrust. Any fluctuation in propeller torque, therefore, shows up also as a variation in thrust at the thrust bearing. Furthermore, the water forces react directly on the hull or sternpost. This causes hull vibrations.

Again, in transmitting a load through gearing, there is a resultant normal reaction at the gear contact teeth and gear bearings which may again excite transverse vibrations in the ship. These effects are not taken into account here because it is believed they do not affect the natural frequency appreciably; while they may contribute a certain amount of damping, they serve to make the vibrations prominent. It is worth noting that in some cases in which these vibrations were, no doubt, excited torsionally from the propeller, all kinds of remedies were tried before changing the propeller exciting frequency from the natural frequency effected a solution (7).

4—Determination of Natural Frequencies of the Propulsion Drive

Critical frequencies are those frequencies at which, in the absence of friction, the system oscillates with no external or applied torques.

The equations of motion are obtained by equating the rate of change of angular momentum of each inertia to the net torque acting on it, then relating the torque of each shaft to the relative angular displacement of its two ends. Referring to Fig. 2, let all the angular displacements, θ_p, θ_0, ... be measured positive in the same direction, and let the torques be positive when they tend to displace the right-hand end of the shaft in the positive direction relative to its left-hand end. Then there result the equations

$$I_2\ddot{\theta}_2 = -T_2 \quad [1]$$

$$I_1\ddot{\theta}_1 = T_2 - T_1 \quad [2]$$

$$I_4\ddot{\theta}_4 = -T_4 \quad [3]$$

$$I_3\ddot{\theta}_3 = T_4 - T_3 \quad [4]$$

$$I_0\ddot{\theta}_0 = T_1 + T_3 - T_0 \quad [5]$$

$$I_p\ddot{\theta}_p = T_0 \quad [6]$$

$$T_2 = K_2(\theta_2 - \theta_1) \quad [7]$$

$$T_1 = K_1(\theta_1 - \theta_0) \quad [8]$$

$$T_4 = K_4(\theta_4 - \theta_3) \quad [9]$$

$$T_3 = K_3(\theta_3 - \theta_0) \quad [10]$$

$$T_0 = K_0(\theta_0 - \theta_p) \quad [11]$$

To solve for the natural frequencies let us seek solutions of Equations [1] to [11], inclusive, in all of which θ_i and T_i vary as $\cos \omega t$. Assume

$$\theta_i = \theta_i \cos \omega t,\ T_i = T_i \cos \omega t \quad [12]$$

This notation, while using θ_i both for the displacement itself as well as the amplitude of the oscillatory displacement, and similarly for T_i, will not lead to any confusion. Physically, the assumption in Equation [12] amounts to finding the steady-state solution only. Variations in speed, if any, are assumed to be slow enough to allow steady state to obtain. Double time differentiation in Equations [1] to [6], inclusive, may now be replaced by multiplication by $-\omega^2$; upon division by $\cos \omega t$ there results a system of algebraic linear homogeneous equations in the unknown amplitudes. In practice one works along the upper branch from the free end toward θ_0 by means of the equations

$$T_2 = I_2\omega^2\theta_2 \quad [13]$$

$$\theta_1 = \theta_2 - T_2/K_2 \quad [14]$$

$$T_1 = T_2 + I_1\omega^2\theta_1 \quad [15]$$

$$\theta_0 = \theta_1 - T_1/K_1 \quad [16]$$

These equations, known as the Holzer equations, follow from Equations [1], [2], [5], [7], and [8] under the assumption in Equation [12], and determine the torques and displacements in terms of θ_2. Similarly, along the lower branch the equations

$$T_4 = I_4\omega^2\theta_4 \quad [17]$$

$$\theta_3 = \theta_4 - T_4/K_4 \quad [18]$$

$$T_3 = T_4 + I_3\omega^2\theta_3 \quad [19]$$

$$\theta_0 = \theta_3 - T_3/K_3 \quad [20]$$

serve to determine the amplitudes in terms of θ_4. From Equations [16] and [20], θ_4 may be determined in terms of θ_2. Proceeding toward the propeller, one obtains from Equations [5] and [11]

$$T_0 = T_1 + T_3 + I_0\omega^2\theta_0 \quad [21]$$

$$\theta_p = -T_0/K_0 + \theta_0 \quad [22]$$

and modifying Equation [6] by the addition of an applied torque T_a, we obtain

$$-T_a = T_0 + I_p\omega^2\theta_p \quad [23]$$

This T_a may be considered as the torque which, applied at the propeller branch, will produce the vibration with θ_i, T_i. With the sign as in Equation [23], a positive T_a tends to displace the propeller in the sense of positive θ_p. At the critical speeds T_a is zero without all the amplitudes vanishing.

The usual method of solution is to assume values of ω^2 and to solve for T_a/θ_2. A graph is made, and where $T_a/\theta_2 = 0$, there $\omega^2 = \omega_c^2$. All calculations may be made on a tabular form sheet. They should be preserved for use in the torque calculations at the criticals which will be discussed later.

5—Damping in the System

Damping in the system is introduced as solid-friction damping, which we imagine to be distributed throughout the shafts. Actually there is also damping at the shrink fits, at the tooth contacts,

in the gears due to the changing stresses there; there is viscous damping in the oil; also windage losses. Since not enough is known about these various types of damping, it does not seem to be worth-while to take account of them individually, and for this reason damping has been introduced as of the solid-friction type, especially in view of the fact that for sinusoidal oscillations there is a comparatively easy way of introducing damping of this kind.

By solid friction is meant the loss of energy in an elastic material that is undergoing a cyclic change of stress. Experimentally it has been found that in such cases there is energy loss per cycle similar to energy loss in material due to magnetic hysteresis; in fact, it is connected with elastic hysteresis because the strain lags slightly behind the stress. When the stress-strain curve for solid material is plotted, there results a narrow loop whose area gives the loss of energy per cycle. This loss of energy in the case of steel, is likely to be a minor fraction φ (<1 per cent) of the maximum elastic energy per amplitude cycle (8). Tests conducted by the General Electric Company on assembled steel structures composed of elements connected by shrinkage fits, bolts, or riveted joints show energy losses from 2 to 10 per cent of the maximum elastic energy per amplitude cycle. It thus appears that the greater part of the damping loss in such an assembly occurs in the fits rather than in the material itself. As a middle value 5 per cent may be considered to be a conservative estimate of what might be expected with coupled shafting and gear-teeth contacts. This value is much higher than the solid-friction energy losses of the solid materials which are used for the shafts and gears, the excess being thought of as due primarily to the energy losses at the coupling fits and tooth contacts where rubbing contact and viscous oil squeezing during oscillations are doubtless responsible for dissipation of energy.

For the case of sinusoidal vibrations, it will now be shown that solid friction can be taken account of by multiplying the stiffness constants K by the factor

$$1 + j\frac{\varphi}{2\pi} = 1 + j\epsilon \qquad [24]$$

In Equation [24] $j = \sqrt{-1}$ and the use of complex numbers is in the sense in which vectors have been employed representing sinusoidal currents or voltages. This is done by assuming that time enters as a factor

$$e^{j\omega t} \qquad [25]$$

rather than as $\cos \omega t$ as in Equation [12], and using complex amplitudes. As known, the passage to the real sinusoids is made by taking the real (or imaginary) part of the complex expression. Since

$$\begin{aligned}(a + jb)e^{j\omega t} &= (a + jb)(\cos \omega t + j \sin \omega t)\\ &= (a \cos \omega t - b \sin \omega t) + j(b \cos \omega t + a \sin \omega t)\end{aligned}$$

it is seen that if the real part is used, a coefficient $(a + jb)$ of $e^{j\omega t}$ leads to the sinusoid $(a \cos \omega t - b \sin \omega t)$. Geometrically, the complex number $a + jb$ can be plotted as a vector, and it may be shown that its length or absolute value

$$|a + jb| = \sqrt{(a^2 + b^2)}$$

represents the amplitude or maximum value of the sinusoid, and $\tan^{-1} b/a$, the angle that the vector makes with the axis of reals, is the phase of the sinusoid.

To justify the foregoing statement concerning Equation [24], imagine a relatively massless shaft with one end fixed and a sinusoid torque applied at the other end. If there is energy lost in friction, then the displacement of the free end will not be in phase with the torque. The 90-deg out-of-phase displacement component will give a velocity term which will be in phase once more with the applied torque, resulting in an energy loss which is thus identified with friction loss.

A way of recognizing this energy loss is by replacing the ordinary torque relation $T = K\theta$ where θ is the total angle of twist in a shaft, by

$$T = K\theta + D\dot{\theta} \qquad [26]$$

where D is a damping constant. If we assume a solution

$$\theta = c \cos \omega t, \dot{\theta} = -c\omega \sin \omega t$$

then

$$T = Kc \cos \omega t - Kc\omega \sin \omega t$$

The work performed by T is

$$\begin{aligned}\int T d\theta &= K\int \theta d\theta + D\int \dot{\theta} d\theta = K(\theta^2/2) + D\int \dot{\theta}^2 dt\\ &= Kc^2 \cos^2 (\omega t/2) + Dc^2\omega^2 \int \sin^2 \omega t dt\end{aligned}$$

The term involving K represents the elastic energy stored in the shaft, an amount $Kc^2/2$ flowing into it as it deflects, and returning as it approaches the equilibrium position. The term involving D leads to a consumption of energy at the average rate $Dc^2\omega^2/2$, hence of amount $Dc^2\omega\pi$ per cycle $\Delta t = 2\pi/\omega$. By definition then

$$\varphi = \frac{Dc^2\omega\pi}{Kc^2/2} = \frac{2D\omega\pi}{K}$$

Hence

$$D = \frac{\varphi K}{2\pi\omega}$$

If imaginary exponentials are used to represent sinusoidal quantities, letting θ and T vary as $e^{j\omega t}$ as in Equation [25], then from Equation [26]

$$Te^{j\omega t} = Kce^{j\omega t} + Dj\omega ce^{j\omega t}$$

or omitting the factor $e^{j\omega t}$

$$T = \left(K + K\frac{\varphi j}{2\pi}\right)\theta = K\left(1 + j\frac{\varphi}{2\pi}\right)\theta = K(1 + j\epsilon)\theta$$

This shows that complex numbers may be used to account for internal damping by replacing K by $K(1 + j\epsilon)$. It may be shown that this results in elliptical hysteresis curves.

It is customary to represent viscous friction by a term proportional to the velocity and thus similar to $D\dot{\theta}$ in Equation [26] with a constant D. Resistance due to such friction is sometimes called "ohmic resistance" due to its similarity to electrical resistance. If D were constant, then the energy loss per unit time would be constant and independent of ω. By letting D vary as $1/\omega$, the constant energy loss per cycle has been obtained.

6—Propeller Damping

It seems curious at first thought that the propeller which causes the vibration should also contribute to its damping. Yet this is the case and it may be seen as follows:

From the propeller torque-speed curve for equilibrium conditions, shown in Fig. 3, it will be noted that if, as a result of a torsional vibration the propeller speed ω_p oscillates about a mean value at P_1, the driving torque also oscillates and in phase with the propeller speed. The variable component of torque is

$$D_p\omega_p \qquad [27]$$

where the damping coefficient D_p is the slope of the torque-speed curve.

The foregoing argument supposes that for a rapid variation of propeller speed the torque of Fig. 3 is followed. Actually this curve represents the load on the propeller when it is held at various constant speeds, while the ship velocity and the propeller

slip have adjusted themselves to their respective constant values corresponding to this constant velocity of the propeller. If the variation in propeller speed is rapid, the ship velocity will not have time to change and only a variation in the propeller slip will result. For this reason the coefficient D_p should be the slope of the propeller torque-speed curve when the ship's velocity with respect to the water or the speed of advance remains constant. This curve is steeper than the equilibrium curve and is indicated by the dashed line in Fig. 3.

Three methods have been suggested for estimating the value of D_p.

1 *Model Experiments.* F. M. Lewis (9) has derived the following expression for the damping factor

$$D_p = \frac{60}{2\pi} \frac{Q(1 - s)}{N} \frac{\partial Q_m/\partial s}{Q_m}$$

where Q is torque, N is propeller speed in rpm, and s is the slip. The subscript m refers to a model propeller which simulates the actual one; s is the same for both the model and the ship. The quantity $(\partial Q_m/\partial s)/Q_m$ can be evaluated from the proper diagram included in Figs. 185–208 of D. W. Taylor's "Speed and Power of Ships" (first edition) (10).

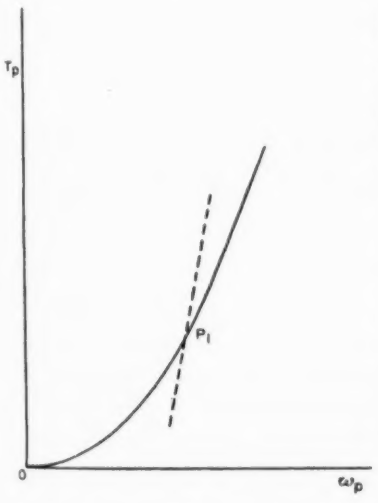

FIG. 3 PROPELLER TORQUE-SPEED CURVE

This method requires a knowledge of propellers and a certain skill is involved in adjusting model experimental data to the propeller on the ship. Furthermore, the data are not available for many propellers of recent design.

2 *Method of Tingey.* The actual torque-speed curve for constant speed of advance can be obtained from a Troost diagram. This has been suggested and developed by R. H. Tingey, chief engineer of the Shipbuilding Division of the Bethlehem Steel Company. On a Troost diagram there are curves of constant values of δ plotted with pitch ratio as the ordinate and basic variable B_p as the abscissa, where

d = propeller diameter, ft
H_0 = pitch at blade tip, ft
P = shaft horsepower
N = propeller speed, rpm
V = ship speed, knots
V_a = speed of advance of propeller in relation to water at stern in which it is working
b = block coefficient of hull

For single-screw ship $V_a = V[1 - (0.5b - 0.10)]$
For twin-screw ship $V_a = V[1 - (0.5b - 0.16)]$

and

$$B_p = \frac{NP^{0.5}}{V_a^{2.5}}, \qquad \delta = \frac{Nd}{V_a}$$

$$\text{Pitch ratio} = \frac{\text{Propeller pitch}}{\text{Propeller diameter}} = \frac{H_0}{d}$$

It is necessary to select the diagram that most nearly applies.

From a knowledge of the equilibrium conditions, if B_p and δ are known, the pitch ratio can be found; or if any one factor in these three quantities is unknown, it can be determined. The pitch ratio is, of course, constant for a given propeller. With constant V_a, δ and B_p can be determined as functions of N. From B_p the shaft horsepower and consequently the propeller torque can be estimated. The damping constant is the slope of propeller torque for constant speed of advance plotted against propeller speed in radians per second.

Shipbuilders, generally speaking, have access to Troost's diagrams for most propellers of recent design, including some with airfoil sections. Similar diagrams are given in D. W. Taylor's "Speed and Power of Ships" (10), 1933 edition, Fig. 204 for three blades and Fig. 211 for four blades. It can be seen that this method also involves a knowledge of the propeller details.

3 *Double-the-Slope Method.* An approximate value of the damping constant can be taken as twice the slope of the equilibrium torque-speed curve. Incidentally, if only one or two points are known on this curve, it may be assumed that the torque varies as the square of the propeller speed. Double-the-slope method gives damping factors which are conservative at low speeds, where propeller damping is significant, and which may be too large at high speeds, where, however, propeller damping is usually negligible compared with that due to internal solid friction.

Because it is based on the best information that is obtainable, and because it is most direct and involves the fewest assumptions, the Tingey method is unquestionably the most accurate. Often, however, the propeller characteristics are not available and then it is necessary to use the third method.

With the assumption Equation [25] that time enters as an imaginary exponential, Equation [23] is now replaced by

$$-T_a = T_0 + \theta_p(I_p\omega^2 + jD_p\omega) \quad \ldots\ldots [28]$$

7—Direct Determination of Amplitude of Oscillating Torques at the Critical Speeds

By introducing solid-friction and propeller damping in the manner explained in the two preceding sections, the Holzer Equations [13] to [23], inclusive, are modified by having K_i replaced by $K_i(i + j\epsilon)$ thus leading, say, from Equation [14] to

$$\theta_1 = \theta_2 - \frac{T_2}{(1 + j\epsilon)K_2} \quad \ldots\ldots [14a]$$

furthermore Equation [23] is replaced by

$$-T_a = T_0 + \theta_p(I_p\omega^2 + jD_p\omega) \quad \ldots\ldots [23a]$$

To solve for the torques at a critical speed, say $\omega^2 = \omega_i^2$, where this critical had been determined by means of Equations [13] to [23], inclusive, we simply set $\omega^2 = \omega_i^2$ and proceed to determine the various torques and amplitudes in terms, say, of θ_2. After the last equation has yielded T_a in terms of θ_2, the assumed value of T_a is inserted, whereupon all the amplitudes are determined absolutely, rather than relatively to θ_2. In solving Equations [14a] and [23a], use is made of the following approximations

$$\frac{1}{1 + j\epsilon} = 1 - j\epsilon \quad \ldots\ldots [29]$$

which holds since ϵ is a very small quantity, though, of course, more exactly

$$\frac{1}{1 + j\epsilon} = \frac{1 - j\epsilon}{1 + \epsilon^2} \quad \ldots\ldots [29a]$$

This method, while straightforward, is quite laborious due to the introduction of imaginary quantities. At certain critical speeds

it is necessary to use a calculating machine in order to maintain proper accuracy, especially at the junction point of the low-pressure and high-pressure turbine branches. It often happens that these branches involve large (equivalent) inertias and also large torques, but that they oscillate one against the other so that in calculating the torque in the propeller shaft from the previously found torques T_1, T_2, higher accuracy is needed than can be obtained by means of a slide rule. In such cases the approximation in Equation [29] may itself lead to error.

The method of normal coordinates, which will now be taken up, simplifies the calculations considerably.

8—Introduction of Normal Coordinates (11)

Consider linear systems in which the forces or torques are linear in the different coordinates which specify the displacements from equilibrium. Then the potential energy V is quadratic in the displacements. The kinetic energy E is, of course, quadratic in the velocities. By "normal coordinates" of a linear system is meant a set of coordinates for which E and V both reduce to a sum of squares (without product terms). These normal coordinates are proper linear combinations of the original variables, with constant coefficients. Their existence follows from a well-known theorem in algebra which states that two quadratics may be simultaneously reduced to algebraic sums of squares by a proper choice of axes.

The present system is linear in the six variables θ_0, θ_p, θ_1, θ_2, θ_3, and θ_4, as noted from the Equations [1] to [11], inclusive. These θ's, however, are not normal coordinates because product terms occur in the potential energy

$$V = \frac{1}{2}[K_0(\theta_p - \theta_0)^2 + K_1(\theta_0 - \theta_1)^2 + \ldots] + K \ldots \quad [30]$$

even though the kinetic energy

$$E = \frac{1}{2}[I_p\dot{\theta}_p^2 + \ldots + I_4\dot{\theta}_4^2] \quad [31]$$

does involve only squares. If $q_0, q_1, \ldots q_5$ are normal coordinates, then each q is a linear combination of the θ's and when V, E are expressed in terms of the q's, there results

$$V = \frac{1}{2}(A_0q_0^2 + A_1q_1^2 + \ldots) \quad [32]$$

$$E = \frac{1}{2}(B_0\dot{q}_0^2 + B_1\dot{q}_1^2 + \ldots) \quad [33]$$

where $A_0, A_1, \ldots$ and $B_0, B_1, \ldots$ are the proper constants.

Applying Lagrange's equations for motion under no external torques, there results the system of equations

$$\left.\begin{aligned} B_0\ddot{q}_0 + A_0q_0 &= 0 \\ B_1\ddot{q}_1 + A_1q_1 &= 0 \\ &\cdots \end{aligned}\right\} \quad [34]$$

It will be noted that as a result of the nonoccurrence of product terms in both V and E, the variables *separate* completely in the equations of motion. Therefore, the solution of these equations is very simple, being given for each q by

$$q_i = C_i \sin(\omega_i t + \varphi_i),\ \omega_i^2 = A_i/B_i \quad [35]$$

where the constants C_i, φ_i are completely arbitrary. Choosing all C_i but one equal to zero, there results an oscillation of frequency ω_i. Now the q's are given by six linear equations

$$\left.\begin{aligned} q_0 &= L_{0p}\theta_p + L_{00}\theta_0 + L_{01}\theta_1 + \ldots \\ q_1 &= L_{1p}\theta_p + L_{10}\theta_0 + L_{11}\varphi_1 + \ldots \\ &\cdots \end{aligned}\right\} \quad [36]$$

whose solution yields for the θ's linear combinations of the q's

$$\left.\begin{aligned} \theta_p &= M_{p0}q_0 + M_{p1}q_1 + M_{p2}q_2 + \ldots \\ \theta_0 &= M_{00}q_0 + M_{01}q_1 + M_{02}q_2 + \ldots \\ &\cdots \end{aligned}\right\} \quad [37]$$

Hence if each q vanishes except q_i, for which Equation [35] holds, there results a motion which can be described as a free oscillation of frequency ω_i, in which all the inertias oscillate sinusoidally and in phase with the same frequency ω_i.

This shows the physical meaning of the normal coordinates, namely, that each normal coordinate q_i is associated with one of the critical frequencies. Each critical frequency carries with it a certain "shape of oscillation," that is, a definite ratio of amplitudes or a definite position of nodes; and each normal coordinate measures, so to speak, the component of that shape in the actual displacement. The subscripts of the q's can conveniently increase in the order of increasing frequencies.

The exact nature of the q's is not completely determined by the foregoing requirement, since a multiplication of each q by a constant is still possible. To avoid this ambiguity, each q will be chosen as equal to unity corresponding to a displacement in which the propeller displacement θ_p is equal to unity. This is equivalent to putting

$$M_{p0} = M_{p1} = \ldots = M_{p5} = 1 \quad [38]$$

in the first Equation [37] which becomes

$$\theta_p = q_0 + q_1 + \ldots + q_5 \quad [39]$$

Now q_1 carries with it a displacement in which the propeller displacement θ_p is equal to q_1, while all the other θ's have the same ratio to θ_p as the amplitudes in the oscillation of frequency ω_1. However, if all q's but q_1 vanish, then the Equations [37] yield for the displacement $M_{01}q_1, M_{11}q_1, \ldots M_{41}q_1$. Hence the coefficients of q_1 in Equation [37] represent precisely the first "shape of vibration," that is, the amplitudes of the various inertias during the critical frequency ω_1. Similarly for the coefficients of $q_2, \ldots, q_5$. As regards q_0, it corresponds to the degenerate frequency $\omega = 0$ corresponding to a constant displacement of all the inertias or to their uniform rotation, and the coefficients of q_0 in Equation [37] are all equal to unity.

To determine A_i, B_i note first that the ratio A_i/B_i is given by Equation [35]; thus only the A's or the B's need be found. The latter are given by

$$B_i = \left[I_p + I_0\left(\frac{\theta_0}{\theta_p}\right)^2 + I_1\left(\frac{\theta_1}{\theta_p}\right)^2 + \ldots\right] \quad [40]$$

where the ratios are of the amplitudes at the ith critical, thus being equal to proper M's of Equations [37]. To prove this, note from Equation [33] that $B_iq_i^2/2$ is the kinetic energy which is possessed by the system when all q's but q_i vanish. Since this happens during the ith critical oscillation, Equation [40] follows readily. Similarly

$$B_0 = I_p + I_0 + \ldots + I_4 \quad [41]$$

9—Application of Normal Coordinates

The applied torque and the propeller damping will first be taken into account. This is done by applying Lagrange's equations of motion in the presence of external forces, that is

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}_i}\right) - \frac{\partial L}{\partial q_i} = Q_i,\ L = E - V \quad [42]$$

Here, as in Equations [30], [31], [32], and [33], E is the kinetic energy and V the potential energy, and Q_i the "generalized" forces

(or torques) whose effect is not included in V, defined by the fact that

$$\Sigma Q_i dq_i \quad [43]$$

is the work done by these forces during the displacement dq_1, dq_2 .... Since the effect of the applied torque and the friction torque on the propeller is not contained in V, they must both be introduced as an external torque Q. Due to an external torque Q on the propeller the work done during a small displacement $d\theta_0$ ..., $d\theta_p$ is $Qd\theta_p$ or, taking Equation [39] into account $Q(dq_0 + dq_1 + \ldots + dq_5)$. Comparing with Equation [43] it follows that $Q_0 = Q_1 = \ldots = Q_5 = Q$.

That is, each "generalized" external force Q_i is equal to the external propeller torque Q. Now the torque acting on the propeller is given by

$$Q = T_a - D_p\dot{\theta}_p = T_a - D_p(\dot{q}_0 + \dot{q}_1 + \ldots + \dot{q}_5) \quad [44]$$

in view of Equation [39].

Substituting in Equation [42], there result the differential equations

$$\left.\begin{aligned} B_0\ddot{q}_0 + A_0q_0 + D_p(\dot{q}_0 + \dot{q}_1 + \dot{q}_2 + \ldots) &= T_a \\ B_1\ddot{q}_1 + A_1q_1 + D_p(\dot{q}_0 + \dot{q}_1 + \dot{q}_2 + \ldots) &= T_a \\ \cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot & \end{aligned}\right\} \quad [45]$$

Now suppose that time enters as $e^{j\omega t}$ as in Equation [25]. Putting

$$D_p = C\omega \quad [46]$$

replacing A_i by $B_i\omega_i^2$ there results[5]

$$\left.\begin{aligned} q_0B_0(\omega_0^2 - \omega^2) + j\omega^2C(q_0 + q_1 + q_2 + \ldots) &= T_a \\ q_1B_1(\omega_1^2 - \omega^2) + j\omega^2C(q_0 + q_1 + q_2 + \ldots) &= T_a \\ \cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot & \end{aligned}\right\} \quad [47]$$

If it is desired to take solid friction into account, then it will be recalled from Equation [24] that the stiffness constants K_i had to be replaced by $K_i(1 + j\epsilon)$. This will have the effect of replacing A_i by $A_i(1 + j\epsilon)$ and ω_i^2 by $\omega_i^2(1 + j\epsilon)$, thus modifying Equations [47] to

$$\left.\begin{aligned} q_0B_0[\omega_0^2(1 + j\epsilon) - \omega^2] + j\omega^2C(q_0 + q_1 + q_2 + \ldots) &= T_a \\ q_1B_1[\omega_1^2(1 + j\epsilon) - \omega^2] + j\omega^2C(q_0 + q_1 + q_2 + \ldots) &= T_a \\ \cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot & \end{aligned}\right\} \quad [48]$$

By subtracting one equation from another, it will be noted that the ratio of any two q's is uniquely determined. For example

$$\left.\begin{aligned} q_iB_i[\omega_i^2(1 + j\epsilon) - \omega^2] &= q_0B_0[\omega_0^2(1 + j\epsilon) - \omega^2] \\ q_iB_i[\omega_i^2(1 + j\epsilon) - \omega^2] &= q_1B_1[\omega_1^2(1 + j\epsilon) - \omega^2] \\ \cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot & \end{aligned}\right\} \quad [49]$$

These ratios are independent of propeller damping and of the applied torque, depending only on the frequency and on the solid friction.

Equations [48] suffice to solve for q_i and since each q carries with it a set of θ's and T's, this solution enables one to determine any displacement and any torque amplitude. The chief advantage of these equations, however, lies in the ease with which they can be applied to calculations at the criticals. Indeed, say at $\omega = \omega_i$, Equations [49] yield

$$\left.\begin{aligned} q_iB_i\omega_i^2(j\epsilon) &= q_0B_0[\omega_0^2 - \omega_i^2 + \omega_0^2(j\epsilon)] \\ q_iB_i\omega_i^2(j\epsilon) &= q_1B_1[\omega_1^2 - \omega_i^2 + \omega_1^2(j\epsilon)] \\ \cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot & \end{aligned}\right\} \quad [50]$$

Since ϵ is very small compared with

$$\frac{\omega_0^2}{\omega_i^2} - 1, \quad \frac{\omega_1^2}{\omega_i^2} - 1, \quad \ldots\ldots \left(\text{excluding } \frac{\omega_i^2}{\omega_i^2} - 1\right)$$

it follows that at $\omega = \omega_i$, q_i will be very much larger than the other q's. Therefore, at $\omega = \omega_i$ the other q's may in general be neglected in comparison with q_i and Equations [48] reduce practically to

$$q_ij\omega_i^2[C + B_i\epsilon] = T_a \quad [51]$$

Physically, the last result amounts to a statement that at $\omega = \omega_i$ only the corresponding ith critical mode is excited to any appreciable extent. It will be further noted that q_i is limited by the joint friction C and ϵ, due to propeller damping and solid friction, and that the phase of q_i is 90 deg relative to T_a. The mode q_i is limited by frictional "resistance," whereas the other modes are limited by "dynamic impedance," almost entirely.

In absence of friction the simplified Equations [43] or [47] and [41] yield

$$\theta_p = T_a\left[\frac{1}{B_0(\omega_0^2 - \omega^2)} + \frac{1}{B_1(\omega_1^2 - \omega^2)} + \ldots\right] \quad [52]$$

Note that at $\omega^2 = \omega_i^2$ the term involving $\omega_i^2 - \omega^2$ becomes infinite. Hence if

$$\frac{T_a}{\theta_p} = \frac{1}{X} \quad [53]$$

(where X is the quantity in the bracket in Equation [52]) be plotted against ω^2 it will cross the ω^2 axis at $\omega^2 = \omega_i^2$. It is readily shown that the slope of Equation [53] at that point is B_i. This way of calculating B_i is sometimes more convenient than Equation [40], since the curve of Equation [53] is available from the determination of ω_i.

Note from Equation [52] that the term $1/B_i^2(\omega_i^2 - \omega^2)$ of θ_p/T_a, which is responsible for the infinity at ω^2, if plotted by itself, leads to a hyperbola. If the mean value of θ_p/T_a at two points which are equidistant from the asymptote $\omega^2 = \omega_i^2$ be taken, then the result will be practically equal to the sum of the remaining terms of the bracket in Equation [52]. In this way one may obtain the contribution of the remaining modes to, say, θ_p/T_a, provided frictional terms occurring in these nonresonant terms be neglected in comparison with the dynamic impedance.

Similarly, after the contribution to any torque T_n at the critical ω_i^2 due to q_i has been found by multiplying the known ratio of that torque to θ_p at ω_i^2 by q_i as determined from Equation [51], the contribution to T_n due to the other modes, that is, the nonresonant components, may be determined by taking half the sum of the values of T_n/T_a at two points close to and equidistant from the asymptote $\omega^2 = \omega_i^2$.

These nonresonant components are usually small so that high accuracy is not essential. The omission of damping in their computation is further justified by the fact that the torques thus obtained are too high.

These components are either in phase with the exciting torque or else 180 deg out of phase with it; in other words, they do not contain any j. Therefore, in combining the nonresonant components and the resonant components, the absolute magnitude is determined as the square root of the sum of the squares.

10—Tuned Branches

If both the high-pressure and low-pressure branches are tuned so that they have a common frequency (when oscillating against I_0 held fast), then this frequency is also a natural frequency for the system as a whole. This follows from the fact that the criticals of the system are separated by the branch frequencies. In this oscillation the low-pressure branch can oscillate against the high-pressure branch with a node at I_0 and without the propeller par-

[5] The critical ω_0 actually vanishes and has been retained to give Equations [47] a more uniform appearance.

ticipating at all. When this is the case, an applied propeller torque cannot excite the resonant and usually large mode of oscillation and the critical is not felt at all. When the branches are nearly tuned, the resonant mode is excited only to a slight extent.

To prove this, consider Equation [40]. Since in the K_1, K_3 shafts there are nodes very close to I_0, it follows that the amplitudes θ_1, θ_2, θ_3, and θ_4 are very large compared with θ_0. On the other hand, if the propeller branch frequency is not close to the tuned critical, then if there is a node in it, it is not close to I_0; therefore the θ_p/θ_0 is not very large. Hence θ_1/θ_p, $\theta_2/\theta_p \ldots$ are large and the inertia constant B for this critical will be very large, and as exact tuning is approached B will become infinite. The resulting q will therefore be very small or zero, and only the nonresonant modes of vibration will be excited. Thus the torque curve will possess no peak or but a small one at the critical.

If all three branches are tuned to a common frequency, then this frequency can be considered as the equivalent of two natural frequencies of the system in the sense that two frequencies are trapped between the frequencies of the three branches. The algebraic equation for ω^2 for the whole system now has the critical as a double root.

In this case the low-pressure branch can oscillate against the high-pressure branch without involving the propeller or the propeller can oscillate against one of the branches without involving the other branch. There is always a node at the big gear, but the resonant component *is* excited by a propeller torque. The chief characteristic of this mode of tuning is that one has all the criticals over with in a single running range. On the other hand, if there is a slight mistuning of the two branches, then it often happens that it is more advantageous to mistune the propeller branch even further, as this leads to smaller maxima torques.

Systems with tuned branches are often referred to as nodal systems or *nodal drives*. The term was introduced by J. H. Smith (12) who pointed out the advantages of such drives.

11—Summary

After the equivalent inertia and stiffness constants have been found, the critical frequencies of the whole system are located. This is done by assuming values for ω^2 in Equations [13] to [23], inclusive, and calculating progressively the various θ's and T's say, in terms of θ_2. The curve T_a/θ_2 is plotted and the points where it cuts the axis correspond to the critical speeds.

After the critical frequencies have been determined the damping constants D_p, C, and ϵ are found and the torques at the criticals are proceeded with. This is carried out either by means of the modified Equations [13] to [23], inclusive (see Equations [14a] and [23a]) or preferably by the method of normal coordinates.

For definiteness consider the first critical ω_1, and suppose that it is not too close to ω_2. From the preceding calculations the ratio of the θ's and T's say to θ_p, at ω_1, is known. It is then possible to find B_1 from Equation [40]; B_1 may also be found from the slope of T_a/θ_p at ω_1^2 (see Equations [53], [52], and the following discussion). Using Equation [51], q_1 is now determined. By multiplying T_1/θ_p, $T_2/\theta_p \ldots$. (as determined from Equations [13]-[22]) by this value of q_1, the "resonant components" of the torques, T_1, T_2, .. at ω_1, are obtained.

Unless the high-pressure and low-pressure branches are nearly tuned to ω_1, these resonant components represent the torques sufficiently accurately. However, if the high-pressure and the low-pressure branches are nearly tuned to ω_1, then B_1 will be large, q_1 small, and the resonant component of torque small likewise. Under these conditions a calculation of the nonresonant components is desirable. One may, of course, wish to obtain the value of the nonresonant components even when they are small relative to the resonant values. These nonresonant components, say of the torque T_2, neglecting friction, may be obtained by taking the mean of T_2 as found from Equations [13] to [23], inclusive, at two values of ω^2 close to and equidistant from ω_1^2.

In case the critical in question, say ω_1, is quite close to the next critical ω_2 (this will happen if the lowest frequencies of both turbine branches are close to the propeller branch frequency), then Equation [51] may not be sufficiently accurate and Equations [48] and [49] should be used directly. Now it is proper, however, to neglect all the normal coordinates other than q_1 and q_2, resulting in the solution of only two simultaneous equations for q_1, q_2.

At frequencies removed from the critical ones the term "resonant" is no longer relevant. In general, the effect of friction is negligible at such frequencies, the amplitude being limited chiefly by dynamic impedance, and the values derived from Equations [13] to [23], inclusive, can be used.

While it is felt that at the present state of knowledge of damping in the system the introduction of friction as solid friction is entirely satisfactory, it is to be pointed out that the introduction of velocity friction located at the inertias is possible by multiplying the constants B_i by a proper complex number.

In summarizing, we believe that the application of normal coordinates to this problem is convenient from several points of view. Normal coordinates do not represent a universal panacea for all difficulties encountered in this field, nor do they replace in any way the location of the criticals by the ordinary methods. They can be used, however, to eliminate lengthy calculations involving complex quantities, for instance, those that result when friction terms are introduced directly in the equation of motion. By resolving any quantity into a resonant and nonresonant component, normal coordinates afford a clearer picture of what happens at resonance. Such questions as how nearly the shape of vibration at a critical (including friction) agrees with the shape of free vibration in absence of friction are easily answered by examination of the nonresonant components.

Discussion

Measurement of Impact Strains by a Carbon-Strip Extensometer[1]

R. K. Bernhard.[2] It might be of certain interest to supplement the excellent paper of the authors by describing briefly similar tests which the writer made and published[3] in part in 1928. The purpose of the investigation was the determination of the propagation velocity of longitudinal waves in a complete structure and not in a single bar.

The instruments for measuring these waves were essentially the same. However, instead of a carbon-strip extensometer, a special type of carbon-stack extensometer (pickup units) weighing 0.12 lb each and having a gage length of 1 in. were used. The recording instrument was a standard two-mirror oscillograph with a maximum speed of the light-sensitive paper of 16 fps and equipped with an electric-arc light source. The natural frequency of the pickup unit was 2000 cps of the receiver (galvanometer elements) 20,000 cps, both working with half-aperiodic damping. Hence no distortion of the records with respect to amplitude and phase, up to exciting frequencies of $2000 \div 4 = 500$ cps, was to be expected.

The procedure of the investigation was as follows: The extensometers were fixed on the lower chord of a simple beam railroad truss of 115 ft span, one telemeter being attached to the first chord near the left support and the second telemeter to the last chord close to the right support. The distance between the two pickups was 98 ft. The waves were excited by a locomotive approaching the left support via the adjacent dam and stopping suddenly over the left support by applying the brakes as strongly as possible. Thus, a relatively large impulse could be excited on the superstructure. Both pickups recorded simultaneously on the light-sensitive paper the tension-time diagram excited by this impulse. By comparing the corresponding waves, their phase difference indicated the time of the longitudinal stress wave in propagation from the left to the right support. The result revealed a propagation velocity of 14,500 ft-sec^{-1}. The theoretical velocity in steel is $v = \sqrt{\frac{E}{\rho}} = \sqrt{\frac{30 \times 10^6 \times 12^2}{\frac{485}{32.1}}}$ $\sim$ 17,000 ft-sec^{-1}, where E = modulus of elasticity of steel and ρ = density of steel. Hence, the measured value was 17 per cent lower than the theoretical value. A tentative explanation of this time difference might be the retarding effect of parts not contributing to the propagation, i.e., gusset plates, loose rivet connections, etc.

The advantages of the measuring method applied in this manner are:

1 With respect to carbon-stack pickups: No amplification units (electro tubes) for the output of the telemeter are required.

2 With respect to mirror oscillographs: Both records, including the time signal, are obtained on the same light-sensitive paper.

3 Furthermore, no supersensitive film or fast lenses are required, thus simplifying the photographic procedure substantially. Hence, difficulties in timing the release of a limited length of two separate supersensitive films traveling at high speed can be avoided.

Kalman J. DeJuhasz.[4] The investigation of the authors has a considerable value not solely for the information concerning the impact phenomena as such, but beyond that, also for the data covering the entire field of elastic transient phenomena which obey the differential Equation [3] of the paper. Besides elastic rods and springs these also embrace "water hammer" in hydraulic conduits, injection phenomena in Diesel engines, and surges in electric circuits.

The experimental confirmation of the theoretical predictions for impact will strengthen the confidence in applying the theoretical method to cases in which experimental methods are not readily applicable.

At The Pennsylvania State College our interest centers mainly on injection phenomena in Diesel engines. For this research, a graphical method has been developed which is easier to apply and gives a clearer picture than the mathematical analysis. Subsequently this method has been applied also to surges in elastic columns and springs.

For those working in this field, a study of the treatise[5] describing the method and of the several papers given in the accompanying bibliography may be of interest. At this time, only the diagrams of the cases treated by the authors will be given as follows:

1 For two bars of equal length and cross section (Figs. 1, 2, and 3 of the paper) but having flat ends contacting simultaneously over the entire area, the velocity-strain diagram is given in Fig. 1 of this discussion, and the stereograms of velocity and strain, as a function of location and time, in Figs. 2 and 3. Cross sections of these stereograms parallel with the time axis will give the history of velocity, with respect to strain, at any given cross section of the bar. It is readily seen that, after the elapse of $2\,L/a$ interval, the two bars separate, the impacting bar comes to a standstill and the impacted bar will assume the original velocity of the impacting bar.

2 For two bars of equal length and cross section, but with flat ends contacting simultaneously over their entire area, the other end of the impacted bar being fixed (Fig. 5 of the paper), the velocity-strain diagram is given in Fig. 4 of this discussion, and the stereograms of velocity and of strain in Figs. 5 and 6. It shows, in conformity with the experimental results, that the strain of impact doubles on reaching the fixed end, and that the two bars separate after the elapse of $4\,L/a$ interval after the beginning of the impact. The impacting bar will then assume an equal and opposite velocity to that of its original velocity. The negative (tensile) strain shown in Fig. 5 of the paper is not explained by the theory, and on this further explanation is requested.

3 For a stationary, free, long bar impacted by a moving short

bar of equal cross section (Fig. 4 of the paper), the velocity-strain diagram is given in Fig. 7 of this discussion, and the stereograms of velocity and strain in Figs. 8 and 9. It is shown that, in the long bar, compressional and tensional strains alternate with strainless periods.

Allowing for the unavoidable contamination always present in experiments as compared with the pure assumptions of theory, the experimental results confirm the theoretical method. It is suggested, however, that making the impacting ends of the bars spherical introduces a seemingly unnecessary complication into the experiments, which would be avoided by using flat ends, taking all possible care that the impact takes place simultaneously over the entire area.

It may be of interest to state that the case of impacting bars of different cross sections is also readily susceptible of graphical treatment. Such cases have been treated by Boussinesq analytically, and subsequently by L. Bergeron[6] graphically.

J. N. Goodier.[7] The development of strain gages suitable for registering the sudden strains of impact raises the question of what is a suitable means of calibration? The authors have naturally chosen what appears to be the simplest type of impact for which analysis is possible. Nevertheless, even this case, the longitudinal impact of rods, presents difficulties. First, the accepted theory, as used by the authors, involves the assumption of a plane wave, i.e., a wave in which, at a given instant, there are no variations over a cross section of the bar. The wave is supposed to travel at constant velocity without change of form, but this is a consequence of the planeness. Then too, Saint Venant's principle is introduced to justify the transition from the local condition at the rounded end of the bar to the plane wave further on.

As to the first point, wave propagation in rods can be investigated without restriction to plane waves.[8] It is found that only sinusoidal waves, with a wave length long compared with the diameter, are propagated as plane waves with velocity $\sqrt{E/\rho}$. The shorter sinusoidal waves involve variation over the cross section and have velocities varying with the wave length. A group of these waves, if generated, would constitute a nonplane wave which changes in form as it is propagated. Such effects would be pronounced in a wave with a steep front. Possibly, however, the wave forms in the authors tests were not steep on the scale of the diameter.

As to the second point, the question is whether there is any evidence to support the extension of Saint Venant's principle from statical to dynamical stress systems. In view of the properties of short sinusoidal waves, it appears likely that the steepness of the wave front, or the suddenness of the impact, will have some importance. In some photographs of impact waves in a bakelite bar, taken by T. R. Cuykendall at Cornell University, plane waves appeared to be the exception rather than the rule.

Authors' Closure

As Professor De Juhasz suggests, the phenomena would be simpler if it were possible to use flat-ended bars which come into

[6] "Methode Graphique de Resolutions des Problems de Propagation d'ondes Planes," by L. Bergeron, Fifth International Congress for Applied Mechanics, Cambridge, Mass., 1938, pp. 694–699.

contact simultaneously all over their ends. However, the early investigators of impact, notably Saint Venant, attempted to secure this condition, without success and, as is pointed out by Sears in his paper, there are difficulties both practical and theoretical in the way of attainment of this idealized condition. In tests on tension impact we have observed a rise of strain from zero to a maximum within about 20 microseconds, indicating that in this case contact was established fairly rapidly over the impacting surfaces.

As Professor Goodier remarks, the question of calibration under dynamic conditions is a real problem for strain gages. We have recently changed at M.I.T. from carbon strips to gages employing fine wires as the strain-sensitive resistance element, and with these new gages feel confident on the bases of tests made to the present time that the response of these gages is not dependent on the rate of straining, thus allowing the use of the static calibration of the gage, and an electrical calibration of the rest of the equipment. This question is now being actively studied.

With regard to the question of change in wave form as the wave propagates, we may remark that for the only moderately steep wave fronts considered in this paper (several feet in length) any such effect is unimportant even in repeated passages through a 6-ft bar. However, in other experiments in which the wave front was only a few inches long, some evidence of such distortion has been observed, though it is still hardly appreciable in a single passage through a 6-ft bar of this diameter, $1^1/_{16}$ in.

Book Reviews

Mathematical Methods in Engineering

MATHEMATICAL METHODS IN ENGINEERING. By Th. von Kármán and Maurice A. Biot. First edition. McGraw-Hill Book Company, Inc., New York, N. Y., 1940. Cloth, 6 × 9 in., xii and 505 pp., $4.

REVIEWED BY ALBERT E. HEINS[1]

IN recent years there have been many attempts on the part of the pure mathematician to write a textbook on applied mathematics which would fit the requirements of the engineer and physicist. These texts have usually been so written that certain mathematical topics beyond the elements of the calculus are discussed and only superficial applications are indicated. On the whole this procedure has been quite unsatisfactory since there are very few pure mathematicians who appreciate the mathematical requirements of the applied scientist.

The textbook by von Kármán and Biot is unique from several points of view. Both authors are applied mathematicians in their own right. Their work in mechanics, pure and applied, and in similarly related topics has given them a much deeper insight into the mathematical requirements of the engineer. Furthermore instead of forcing mathematical methods to fit physical applications, they build their discussion about one central physical topic, mechanics, and then discuss the various mathematical methods used in this and similarly related fields.

The material which the authors have chosen to discuss forms an excellent intermediate text on mathematics for engineers or physicists. On the mathematical side, we find a discussion of linear and quadratic forms, matrices, ordinary differential equations, certain simple partial-differential equations, boundary value problems, harmonic analysis, transient phenomena, operational calculus, and equations of finite differences. Due attention is given to approximate and graphical methods. These mathematical methods are in turn applied to many interesting problems in dynamics, structures, and related engineering problems. The text is essentially a discussion of mechanics of rigid bodies and continuous media, and some electric-circuit theory. The problems, with the exception of a few mathematical exercises, are drawn mainly from mechanics and to a lesser extent from the electric-circuit theory.

The discussion of mechanics should make a mark for itself with the engineers and the physicists in the same way that the classical text of Paul Appel "Traité de Mécanique Rationelle" has made with the applied mathematicians for the last four decades. The present authors, however, have taken pains to add a more practical flavor and modern dress to their discussion of mechanics than is to be found in Appel's treatise. The authors are to be commended for bringing so many important mathematical methods to the attention of the applied scientist. The book is clearly written and careful attention is given to definitions of mathematical and physical character. The problems are well chosen and graded. Here the student will occasionally meet his Waterloo. Von Kármán and Biot have written a textbook which is a contribution to mathematics as well as to the applied sciences.

Thermodynamics

SPEZIFISCHE WÄRME, ENTHALPIE, ENTROPIE UND DISSOZIATION TECHNISCHER GASE. By E. Justi. Julius Springer, Berlin, 1938. Paper, $10^1/_4$ × 7 in., vi and 157 pp., 43 figures and 116 tables, 19.80 rm.

REVIEWED BY JOHN A. GOFF[2]

FOR many years since the suggestion as to the quantum nature of radiant energy was put forward as a hypothesis by Planck in 1900, the development of the quantum theory has been regarded as the plaything of the physicist. Little of real practical value was expected from this development even by the physicist himself and the attitude of the engineer has been one of indifference and aloofness. But along with the development of the quantum theory have come notable improvements and refinements in the mathematical apparatus of statistical mechanics. The result has been that now the physicist is in a position to predict, in many cases with greater accuracy than that with which the engineer can measure by calorimetric methods, the properties of substances entering into the processes with which the engineer is directly concerned, and to answer questions whose solution by empirical methods would require much time and elaborate experimental apparatus. As one of the first attempts to explain to the engineer the nature of the physicist's predictions, to collect and comprehensively review for him the data already available in the literature, and to suggest what further contributions may be expected in the future, the book under review is indeed timely and valuable.

Of first importance, perhaps, are the predictions of quantum-theory and statistical mechanics regarding the thermodynamic

[2] Dean of Towne Scientific School, University of Pennsylvania, Philadelphia, Pa. Mem. A.S.M.E.

properties of gases at low pressures or, more precisely, at zero pressure. The principal source of the numerical values obtained is the analysis of band spectra. According to the quantum theory, the frequency ν of each observed spectral line corresponds to a transition from one energy level to another such that $\Delta\epsilon = h\nu$, where h denotes Planck's constant. When the various modes of internal motion of which the molecules of a gas are capable have been enumerated and analyzed, it is usually possible to "integrate" the spectrum in such a way as to obtain for each individual mode a series of energy levels ϵ_i which, beginning with an undeterminable "ground-level" value ϵ_0, increase by integral multiples of the energy quantum appropriate to that particular mode. The author briefly describes the various methods of determining these energy levels from spectroscopic measurements.

Having determined the whole series of energy levels for each mode of internal motion, the problem is to estimate the fraction of all molecules occupying each level at any given temperature. Statistical mechanics solves the problem by showing how to construct for each mode a "partition function" Z such that the contribution to the free energy, $F = U - TS$, of an aggregate of N molecules in statistical equilibrium within a volume V is

$$\Delta F = -kNT \ln Z$$

where k denotes Boltzmann's constant. The form of the partition function, except in the case of translational motion, is

$$Z = e^{-\epsilon_0/kT} \sum_{i = 0,1,2 \ldots} e^{-\frac{\epsilon_i - \epsilon_0}{kT}}$$

Applying the identical relations of thermodynamics in order to determine the corresponding contributions to the energy U and entropy S and examining the results, one obtains deductions of practical as well as theoretical importance.

In the first place it appears in accordance with the reasoning of classical thermodynamics that the contribution to the energy can only be evaluated to within an additive constant quantity $N\epsilon_0$ which is the value of the energy contribution at absolute zero ($T = 0$). In the second place, however, the corresponding entropy contribution is entirely independent of the value assigned to $N\epsilon_0$ and indeed its value at absolute zero is absolutely zero.

The last deduction evidently contains the essence of the so-called Third Law of thermodynamics, but in attempting to correlate it with direct experimental data complications often arise. Thus, there may be energy separations satisfying the inequality $\epsilon_i - \epsilon_0 \ll kT$ at the lowest experimentally accessible temperatures and, if so, the contribution to the entropy will still have a finite value at these temperatures. Such "degeneracy" or "multiplicity of the ground level" actually occurs in the rotational levels (except in the case of hydrogen), also in the vibrational, electronic, and nuclear-spin levels. And there are other ways in which observations at accessible temperatures on actual gases must be corrected. To mention only one, even at the lowest accessible temperatures, ordinary hydrogen remains a mixture of two allotropic modifications though if held at still lower temperatures for a sufficiently long time or properly catalyzed the modification with nuclear spins symmetrical would presumably disappear and the entropy contribution would tend to vanish in accordance with the Third Law. The author mentions the more important of these corrections, but his discussion leaves much to be desired.

The final step leading to absolute values of entropy for a gas is the analysis of the contribution from translatory motion. In this case also statistical mechanics predicts "degeneracy" so that even though the entropy contribution remains finite down to extremely low temperatures, possibly of the order of 0.001 deg K, nevertheless at still lower temperatures it tends to vanish in accordance with the Third Law. At temperatures above this range of degeneracy the entropy contribution from translational motion is correctly given by the Sackur-Tetrode equation. It is the only contribution which depends upon the volume.

In the second part of chapter 3 the author assembles and discusses the available data on something like forty different gases. Wherever comparison with direct calorimetric determinations of specific heat is of value or special interest, such comparison is made. The Third Law as first formulated by Nernst and later reformulated by Lewis and Randall was intended to apply only to the crystalline solid state. Again statistical mechanics has shown the necessity of applying corrections in many cases for the existence of energy separations $\epsilon_i - \epsilon_0 \ll kT$ at the lowest experimentally accessible temperatures, but when such corrections have been estimated and applied the entropy of the solid at absolute zero may be taken to be absolutely zero as in the case of gases. This provides the basis of a most interesting comparison between the value of the entropy for a gas obtained from analysis of its band spectrum, and that obtained by extrapolating low-temperature specific-heat data on the solid phase to absolute zero for a starting point, adding entropies calculated from observed specific heats and latent heats through vaporization, and finally adding a correction for the effect of intermolecular forces which may be appreciable if the resulting vapor pressure is not sufficiently low. In all cases where the requisite calorimetric data are available, the author makes this comparison and thereby increases confidence in the accuracy of the predictions of statistical mechanics.

Yet another comparison is obtained from vapor-pressure measurements which the author discusses though not with too much clarity. Unfortunately, also, in the tables many errors have been carried over from the original sources and a number have been added so that the reader must exercise considerable discretion in the use of the data listed. Thus the values listed for monatomic hydrogen in Table 86 are not "Reduced Free Enthalpy" as stated, for they omit the contribution from electron spin and part of the Sackur-Tetrode constant. Again the data in Table 51b for CO are all in error in view of subsequent recalculations.

The collection and discussion of the data from spectroscopic measurements is doubtless the most valuable part of the book, though scarcely less valuable is the matter of chapter 2. Here one finds an excellent discussion of the empirical equations of state of van der Waals and of Berthelot, particular attention being given to the latter by way of comparison with direct experimental data. There is also a discussion of the semiempirical equations of Callendar, Wohl, and Beattie-Bridgeman. The evident purpose of these discussions is to provide means of correcting the spectroscopic data, which are strictly applicable at zero pressure only, to allow for the effect of intermolecular force which enters at moderate to high pressures.

Finally, the author makes a real contribution to the thermodynamics of gas mixtures by clearly stating the problem and then briefly summarizing what has been accomplished to date in the way of verifying the various proposed combination rules for evaluating the so-called interaction constants.

The book is well documented and, as stated, presents a timely and valuable treatment of a subject which is destined to find increasing application in engineering.

Errata

In Table 1 on page A-39 of the March, 1940, issue of the Journal of Applied Mechanics the figures for specific damping capacity should in every case be twice the corresponding figures for logarithmic decrement, instead of one half, so that the correct figures for damping capacity are four times those which appear in this column.

The Impact of a Mass Striking a Beam

By E. H. LEE,[1] STANFORD UNIVERSITY, CALIF.

The integral equation for the horizontal impact of a mass on a beam was developed by Timoshenko in 1912. He showed that any such impact problem can be solved provided sufficient patience and tenacity are applied in using the tedious numerical method of solution by dividing the time into small increments during which the contact force can be considered constant. This method is too lengthy to be applied in practice, and moreover, a solution is required giving characteristics of the impact as a whole, rather than slowly progressing through its duration with no indication of the future development of the impact.

In the first part of this paper a concise approximate solution is developed, making the assumptions that the duration of contact is small in comparison with the period of the fundamental mode of vibration of the beam, and that only the fundamental mode of oscillation of the beam need be considered. Results obtained by this method are checked against those determined by the lengthier numerical method. Good agreement is reached in some examples, but other results show large errors, both in the contact compression force and in the resulting motion.

Light was brought to bear on this difficulty by using a solution based on energy and momentum considerations, giving a curve which supplies a rapid determination of the distribution of energy among the various modes of vibration of the beam. This curve gives directly the condition for the vibrational energy developed in the beam, due to the impact, to be confined mainly to the fundamental mode. This is shown by examples to be the required condition for the validity of the previous approximate method.

The solution using energy and momentum considerations is developed to give the motions of the beam and mass resulting from the impact (free vibrations in the beam and uniform velocity of the mass) so that the subsequent development of the impact can be ascertained and repeated impacts dealt with. The investigation also gives the deflection curves of the beam produced by the impact; these show a wide deviation from static-deflection curves.

NUMEROUS attempts have been made to determine the stresses and deflections produced when a mass strikes a beam. The most popular approach has been from energy considerations, using the transformation of the kinetic energy of the striking mass into potential energy of bending in the beam, with some estimate of energy loss due to impact. Saint Venant (1)[2] carried out a more thorough investigation in which he assumed that, immediately on contact, the mass became part of the beam and moved with it. He considered the general problem of the modes of vibration of the beam and attached mass, from which he obtained the special solution satisfying the initial condition of impact, the mass moving with velocity v_0 and the beam at rest.

A completely satisfactory equation of motion was evolved by Timoshenko (2) using only justifiable assumptions. This equation includes the effect of local elastic deformation at the point of contact using the relationship $\alpha = kF^{2/3}$ developed by Hertz (3), where α is the relative approach of the two bodies in contact, F is the compression force between them, and k is a constant depending on the radii of curvature at contact and on the elastic properties of the bodies. This relationship is strictly true for static loading only. However, since the time for stress waves to traverse the region of contact is extremely small compared with the duration of contact in an impulse, sensibly equilibrium conditions obtain in this region and the Hertz relation holds good. A further simplification is that the vibration of the striking mass can be neglected. Rayleigh (4) showed that very little vibration is induced in an oscillating system under the influence of forces of duration long in comparison with its natural periods. This condition is obeyed by the striking mass since the natural frequencies of a solid body are extremely high, thus eliminating the necessity of considering its vibration.

The theory of horizontal[3] impact on beams can be developed in a general manner for impact at any point along the length of a beam and for various conditions of support. To simplify the theory, the problem of central impact on a uniform beam simply supported at its ends, as shown in Fig. 1, is considered in the body of this paper, the general case being dealt with briefly in the appendix.

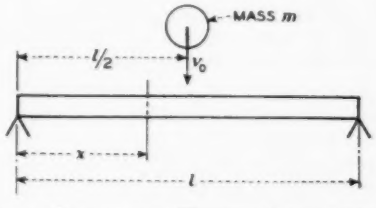

FIG. 1 CENTRAL IMPACT ON A UNIFORM BEAM SIMPLY SUPPORTED AT ITS ENDS

In order to simplify subsequent elaborations, the fundamental integral equation is developed. It represents mathematically the equality between the approach of the mass and the beam in terms of their relative motion, and the approach as deduced from Hertz's law, $\alpha = kF^{2/3}$.

Measuring displacements from the positions of the mass and the beam when contact commences, s denotes the displacement of the striking mass and η that of the center of the beam. Then the relative approach α, as shown in Fig. 2, is

$$\alpha = s - \eta \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots [1]$$

This paper is an abstract of a thesis having the same title and submitted to Stanford University, June, 1940, in partial fulfillment for a Ph.D. degree.

Presented at the National Meeting of the Applied Mechanics Division, Ann Arbor, Mich., June 20–21, 1940, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 10, 1941, for publication at a later date. Discussion received after closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[3] Horizontal impact is discussed to eliminate gravity considerations. Actually, the impact duration is so brief that gravity would have no appreciable effect on the motion during impact so that the theory developed can also be applied to problems of vertical impact.

The term $F(\tau)$ represents the contact compression force as a function of the time, in terms of which the displacements of the mass and the beam can be expressed. Denoting the mass of the striking body by m, the diminution of its velocity during the interval $d\tau$ is $[F(\tau)/m]d\tau$, which contributes a decrease in the displacement at the time t equal to $[F(\tau)/m]d\tau(t - \tau)$. Thus the displacement at the time t is given by

$$s = v_0 t - \frac{1}{m}\int_0^t F(\tau)(t-\tau)d\tau \quad [2]$$

where v_0 is the initial velocity of the striking body.

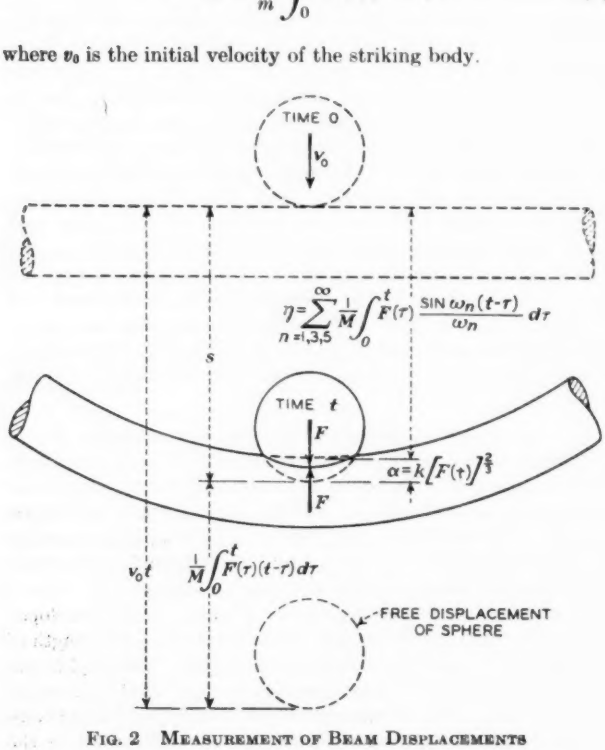

FIG. 2 MEASUREMENT OF BEAM DISPLACEMENTS

The forced vibrations produced in the beam by the varying force $F(\tau)$ at the point of contact are expressed in terms of the normal modes of vibration. In the case of symmetrical vibration of a simply supported beam, the normalized characteristic deflection functions[4] are $\sqrt{(2/l)}\sin(n\pi x/l)$ for $n = 1, 3, 5$, etc., where x is the coordinate of position along the beam of length l. The corresponding angular frequencies of the natural modes of vibration are ω_n, related by the equation $\omega_n = n^2\omega_1$.

The central deflection η due to the forced vibrations is given by (5)

$$\eta = \sum_{n=1,3,5}^{\infty} \frac{2}{ql}\int_0^t F(\tau)\frac{\sin \omega_n(t-\tau)}{\omega_n}d\tau \quad [3]$$

where q is the constant mass per unit length of the beam. $ql/2$, denoted by M, is called the reduced mass and in this particular case is equal to half the mass of the beam.

Substituting Equations [2] and [3] in Equation [1] gives the integral equation for the contact force variation from which the motion can be determined, that is

$$k[F(t)]^{\frac{2}{3}} = v_0 t - \frac{1}{m}\int_0^t F(\tau)(t-\tau)d\tau - \sum_{n=1,3,5}^{\infty}\frac{1}{M}\int_0^t F(\tau)\frac{\sin \omega_n(t-\tau)}{\omega_n}d\tau \quad [4]$$

Due to the nonlinear term, $kF^{\frac{2}{3}}$, direct solution is possible only by a tedious numerical method. The duration of the impact is subdivided into small increments of time during which F can be considered constant for the purpose of integration. Knowing that F is always positive and initially zero, the solution can be developed using a step-by-step process in which the value of F at the end of an interval is obtained in terms of the integrals on the right-hand side of Equation [4] determined by numerical methods.

Although this method is very lengthy, it does supply a possible solution of any impact problem, sufficiently small time intervals providing any desired degree of accuracy. Characteristics of various types of impact are shown in the solution of different problems, but this method does not indicate the general factors leading to these special characteristics. For example, it is found that in certain circumstances the complete impact consists of a succession of separate rapid impacts; the whole occurs in a very short time and appears as one contact to an observer. This process can be easily visualized in the case of a large mass striking a beam. At the first impact, the relatively light beam bounces off the oncoming mass, only to have its motion reversed by its own elasticity and thus encounter repeated impacts, until the velocity of the mass is reversed and it leaves the region of vibration of the beam. That such repeated impacts occur has been shown experimentally by Mason (6), Arnold (7), and Tuzi and Nisida (8). This type of impact is indicated in the step-by-step solution of certain problems; but it would be quite impossible to solve a sufficient number of cases with different masses, natural frequencies, and contact surfaces, in order to arrive at general conditions for its occurrence. In order to study such characteristics, recourse must be made to solutions in terms of functions of time, even if they can only be obtained under certain restrictions.

APPROXIMATE SOLUTION ASSUMING SHORT IMPACT DURATION

J. Lennertz (9) developed a concise method of solution by considering each impact as a whole rather than as a succession of steps, but the method is restricted by additional assumptions. He assumed that the duration of contact is small compared with the period of the fundamental mode of vibration of the beam and also that the fundamental mode only is stimulated into activity. The first assumption is justified in most impact problems and, moreover, is easily checked, but the decision whether or not it is permissible to neglect the effect of the higher modes of vibration of the beam is more difficult. The latter assumption is equivalent to replacing the beam by the one-

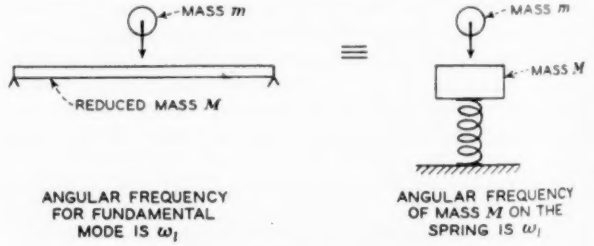

FIG. 3 ASSUMPTION FOR THE APPROXIMATE SOLUTION

[4] The characteristic function $u(x)$ of a mode of vibration is normalized by multiplying it by a constant so that $\int_0^l [u(x)]^2 dx = 1$. In vibration theory, normalized characteristic functions are used to simplify the algebra.

degree-of-freedom system of a mass on a spring as shown in Fig. 3.

The method developed in this paper is an improvement and further development of the one used by Lennertz, since his solution did not utilize the best approximations, and in addition contained some errors. His basic assumptions are retained.

The method of solution is to assume a sinusoidal contact-force variation $F = K \sin \lambda\tau$ which enables the integrals in Equation [4] to be evaluated, thus transforming it into an algebraic equation. Values of K and λ are required which satisfy this equation for all values of the time t during the impact. Having made some simplifying approximations, two simultaneous equations for K and λ are obtained by equating coefficients of $\sin \lambda t$ and t, so that the equation is satisfied for all t. The approximate value of F so obtained can be improved by a method of successive approximation.

Since $F = K \sin \lambda\tau$ cannot become negative, contact occurs for $0 < \lambda\tau < \pi$, so that the duration of contact is $T_D = \pi/\lambda$ sec.

Substituting the sinusoidal variation for F and evaluating the integrals, Equation [4] becomes

$$k(K \sin \lambda t)^{3/2} = v_0 t - \frac{K}{m}\left(\frac{t}{\lambda} - \frac{1}{\lambda^2}\sin \lambda t\right) - \frac{K}{M}\frac{\lambda \sin \omega_1 t - \omega_1 \sin \lambda t}{\omega_1(\lambda^2 - \omega_1^2)} \quad [5]$$

bearing in mind the initial assumption that only the fundamental mode of vibration is to be considered.

Equation [5] is still too complicated for direct solution. Some simplification can be made by writing $\omega_1 t$ for $\sin \omega_1 t$, since $\omega_1 t$ remains small. This results from the assumption that the impact duration π/λ is short compared with the period $2\pi/\omega_1$ of the fundamental mode. In addition the $\sin^{3/2} \lambda t$ in $k(K \sin \lambda t)^{3/2}$ can be approximated by $A \sin \lambda t$; where A is chosen so that the new contact-force variation, which makes $\alpha = kK^{3/2}A \sin \lambda t$, produces the same total change of momentum in the striking mass as did $K \sin \lambda t$. This condition expressed mathematically becomes $\int_0^\pi \sin \theta d\theta = A \int_0^\pi \sin^{3/2} \theta d\theta$ which gives $A = 1.093$.

Inserting these simplifications, Equation [5] becomes

$$kK^{3/2}A \sin \lambda t = v_0 t - \frac{K}{m}\left(\frac{t}{\lambda} - \frac{1}{\lambda^2}\sin \lambda t\right) - \frac{K}{M}\frac{1}{\lambda^2 - \omega_1^2}(\lambda t - \sin \lambda t) \quad [6]$$

Equating the coefficients of $\sin \lambda t$ and t on each side gives two simultaneous equations for the determination of K and λ, that is

$$\left.\begin{aligned} 0 &= v_0 - \frac{K}{m\lambda} - \frac{K}{M}\frac{\lambda}{\lambda^2 - \omega_1^2} \\ kK^{3/2}A &= \frac{K}{m\lambda^2} + \frac{K}{M}\frac{1}{\lambda^2 - \omega_1^2} \end{aligned}\right\} \quad [7]$$

Eliminating K

$$\lambda^5 = v_0 \frac{[(m + M)\lambda^2 - M\omega_1^2]^2}{A^3k^3m^2M^2(\lambda^2 - \omega_1^2)^2} \quad [8]$$

A good approximation for λ can be obtained from this equation by first obtaining λ_1 when ω_1^2 is neglected in comparison with λ^2

$$\lambda_1^5 = v_0 \frac{(m + M)^2}{A^3k^3m^2M^2} \quad [9]$$

Now λ_1 is substituted in Equation [8] to obtain λ_2 which will be a good approximation to the correct value of λ.

Then K is determined from the first of the simultaneous Equations [7] which transforms into

$$K = v_0 \frac{mM\lambda(\lambda^2 - \omega_1^2)}{(m + M)\lambda^2 - M\omega_1^2} \quad [10]$$

The value thus obtained for contact pressure $K \sin \lambda\tau$ can be improved by using a method of successive approximation derived directly from Equation [4]. If $F_\mu(\tau)$ is an approximate solution of the integral equation, then a better[5] approximation $F_{\mu+1}(\tau)$ can be obtained from the equation

$$k[F_{\mu+1}(t)]^{3/2} = v_0 t - \frac{1}{m}\int_0^t F_\mu(\tau)(t - \tau)d\tau - \sum_{n=1,3,5}^{\infty}\frac{1}{M}\int_0^t F_\mu(\tau)\frac{\sin \omega_n(t - \tau)}{\omega_n}d\tau \quad [11]$$

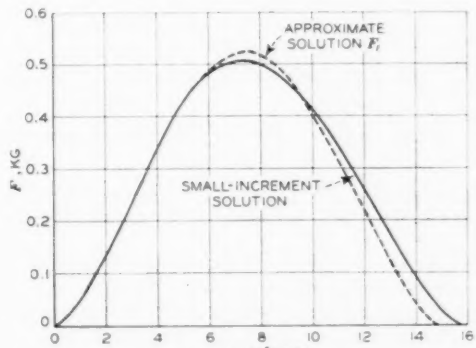

FIG. 4 COMPARISON OF CONTACT-FORCE VARIATIONS USING TIMOSHENKO'S SMALL-INCREMENT METHOD AND THE AUTHOR'S APPROXIMATE SOLUTION

In adopting this process of successive approximation, the first step is to find F_1 when $F_0 = K \sin \lambda t$. In the theory developed in the foregoing, the right-hand side of Equation [11] for $F_0(\tau) = K \sin \lambda\tau$, was equated to $kK^{3/2}A \sin \lambda t$, as shown by Equation [6]. Thus Equation [11] reduces to

$$kF_1^{3/2}(t) = kK^{3/2}A \sin \lambda t$$

or

$$F_1(t) = KA^{2/3} \sin^{3/2} \lambda t \quad [12]$$

But $F_2(\tau)$, a better approximation, can be obtained by expressing $\sin^{3/2} \lambda t$ in a Fourier series for evaluation of the integrals on the right-hand side of Equation [11] when $\mu = 1$. In most cases the assumptions on which the method is based do not justify the expenditure of the time required to calculate $F_2(\tau)$.

Results, obtained by applying this approximate method to the problem solved by Timoshenko (2) using the lengthy small-increment procedure, agree well as shown in Fig. 4. In this problem $m = 32.24$ grams, $M = 61.1$ grams, $v_0 = 1$ cm per sec, and $\omega_1 = 2\pi\ 10^3\ \text{sec}^{-1}$.

Fig. 5 shows the contact-force variation obtained in three different ways for the case of a 50-lb weight striking a beam of total weight 298.5 lb. The angular frequency of the fundamental mode of vibration is 531 sec^{-1} and the initial velocity of the

[5] For a nonlinear equation the convergence of this process is somewhat indefinite, but it appears to be convergent if $F_0(\tau)$, the first approximation, is reasonably close to the correct force variation. For a linear equation this procedure is convergent whatever expression is chosen for $F_0(\tau)$.

striking mass is 11 fps. This problem was solved by the small-increment method taking 360 intervals during the period of the fundamental mode. The solution was obtained in this manner both for the actual conditions when all the modes of vibration can be excited, and for the related problem dealing with a system of one degree of freedom corresponding to the fundamental mode of the beam. Fig. 5 shows that the approximate method of solution developed in this section gives a force variation $F_1(\tau)$ lying

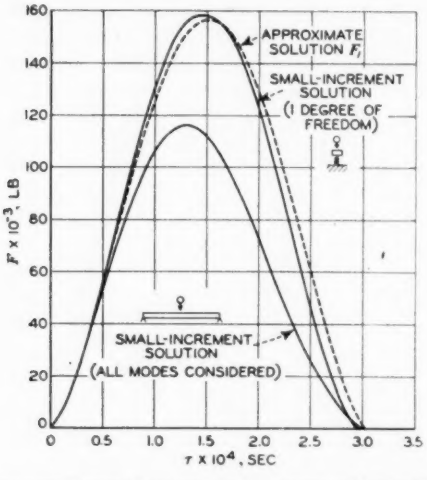

FIG. 5 CONTACT-FORCE VARIATIONS OBTAINED IN THREE DIFFERENT WAYS FOR THE CASE OF A 50-LB WEIGHT STRIKING A 298.5-LB BEAM

very close to that obtained using the small-increment solution for the one-degree-of-freedom system. These curves, however, show much larger contact forces than are developed during impact on a beam when all the modes of vibration can be stimulated. This indicates that for the particular problem considered, the error in the solution lies not in the mathematical approximations adopted but in the physical assumption that only the fundamental mode of the beam affects the impact process.

From this example it is clear that if this approximate method of solution is to prove useful, some criterion must be found which will give conditions justifying the assumption of the equivalence of a one-degree-of-freedom system. Such a criterion is evolved from the energy considerations of the following section.

SOLUTION BY ENERGY AND MOMENTUM CONSIDERATIONS

An important contribution to the understanding of impact characteristics was made by Zener and Feshbach (10) in their considerations of energy transfer. By combining the principle of conservation of energy[6] during the impact, and momentum considerations for the striking mass, the resulting velocity of the mass was determined and also the vibrational energy developed in the beam. Solution of the nonlinear integral Equation [4] was replaced by assuming a function for the time variation of the contact force normalized in such a way that the final motion was insensitive with respect to the choice of this function.

In the present paper this manner of handling the problem is further developed to probe more deeply into the impact process, leading to a simple determination of the energy spectrum of the beam (i.e., the distribution of energy between the normal modes of vibration) and also giving the resulting motion of the beam and striking mass. The former consideration has an important bearing on the validity of the previous approximate solution, leading to conclusions which are confirmed by the few specific impact problems which have been solved by the reliable but lengthy small-increment method.

The procedure in the application of the principle of conservation of energy is to assume a contact-force variation in terms of which the energy imparted to the beam can be represented. An equation is obtained by writing this energy expression equal to the kinetic energy lost by the mass. Using momentum considerations for the striking mass, the force variation is transformed into a normalized function which largely eliminates errors due to the arbitrary choice of the force function. The energy equation then gives directly the rebound velocity of the mass and the energy absorbed by the beam.

Any symmetrical vibration of a simply supported beam can be expressed (11) as a series of characteristic functions in the form

$$u(x,t) = \sum_{n=1,3,5}^{\infty} C_n(t) \sqrt{\frac{2}{l}} \sin \frac{n\pi x}{l} \quad \ldots\ldots [13]$$

where $u(x,t)$ represents the displacement of the section at the distance x from the end of the beam, and at the time t; $C_n(t)$ is the generalized coordinate of the nth mode of vibration.

If a force variation $F(t)$ is applied at the center of the beam, normal to its length, the generalized force stimulating the nth mode is given by $F(t)\sqrt{(2/l)}\sin n\pi/2$ which reduces to $\sqrt{(2/l)}(-1)^{(n-1)/2}F(t)$, and the corresponding differential equation determining the motion is

$$\frac{d^2C_n}{dt^2} + \omega_n^2 C_n = \frac{1}{q}\sqrt{\frac{2}{l}}(-1)^{\frac{n-1}{2}} F(t) \quad \ldots\ldots [14]$$

where q is the mass per unit length of the beam.

Assuming the beam to be initially at rest at the time t_0, when the force commenced to act, the solution of this equation giving the vibration produced in the nth mode is

$$C_n(t) = \sqrt{\frac{2}{l}} \frac{(-1)^{\frac{n-1}{2}}}{\omega_n q} \int_{t_0}^{t} \sin \omega_n(t-\tau) F(\tau) d\tau \quad \ldots [15]$$

The development of this solution is similar to the development of Equation [3].

The vibrational energy absorbed by each mode is composed of the sum of kinetic energy and strain energy of bending at a particular time. The kinetic energy for the nth mode is equal to $(q/2)(dC_n/dt)^2$, the strain energy equals $(q/2)\omega_n^2 C_n^2$ making the total energy, ΔE_n, equal to

$$\Delta E_n = \frac{q}{2}\left[\left(\frac{dC_n}{dt}\right)^2 + \omega_n^2 C_n^2\right] \quad \ldots\ldots [16]$$

Substituting the value of C_n from Equation [15], the energy absorbed by each mode during impact is

$$\Delta E_n = \frac{1}{ql}\left|\int_{t_0}^{t_1} F(\tau) e^{i\omega_n \tau}\, d\tau\right|^2 \quad \ldots\ldots [17]$$

where t_1 is the time when contact ceases.

Errors resulting from ignorance of the contact-force variation $F(\tau)$ can be largely eliminated by expressing $F(\tau)$ in the form of a normalized force. To this end e, a restitution coefficient, is defined by expressing the rebound velocity of the striking mass in the form ev_0, which is positive when its direction is opposite to that of the initial velocity v_0. The total change in the momentum of the mass produced by the contact force is then

$$mv_0(1+e) = \int_{t_0}^{t_1} F(\tau) d\tau \quad \ldots\ldots [18]$$

[6] Throughout this paper elastic impact is considered, assuming that the stress in the contact region does not exceed yield-point stress. Although energy is conserved, the usual concept of loss of kinetic energy by the striking mass holds good, the "lost" energy going into vibration of the beam.

Now, defining the normalized contact force $\mathfrak{F}(\tau)$ by the relation $F(\tau) = mv_0(1 + e)\mathfrak{F}(\tau)$, the momentum Equation [18] becomes

$$\int_{t_0}^{t_1} \mathfrak{F}(\tau)d\tau = 1 \quad \ldots\ldots [19]$$

The advantage of this transformation is that only the shape of the $\mathfrak{F}(\tau)$ curve is arbitrary, the scale being restricted by the condition $\int_{t_0}^{t_1} \mathfrak{F}(\tau)d\tau = 1$, thus minimizing errors in assuming an expression for the contact-force variation. Substituting for $F(\tau)$, Equation [17] becomes

$$\Delta E_n = \frac{m^2v_0^2(1 + e)^2}{ql}\left|\int_{t_0}^{t_1} \mathfrak{F}(\tau)e^{i\omega_n\tau}d\tau\right|^2 \quad \ldots\ldots [20]$$

The total vibrational energy of the beam is equal to the sum of the energies in the separate modes of vibration, i.e., the total vibration energy $\Delta E = \sum_{n=1,3,5}^{\infty} \Delta E_n$.

In order to simplify the development, the function R is introduced, and defined by the equation

$$R = \frac{m}{M}\sum_{n=1,3,5,}^{\infty}\left|\int_{t_0}^{t_1} \mathfrak{F}(\tau)e^{i\omega_n\tau}d\tau\right|^2 \quad \ldots\ldots [21]$$

where $M = ql/2$ is the reduced mass of the beam. The total vibrational energy ΔE now reduces to

$$\Delta E = \sum_{n=1,3,5}^{\infty} \Delta E_n = \frac{1}{2}mv^2_0(1 + e)^2R = E(1 + e)^2R \ldots [22]$$

where E represents the initial kinetic energy of the striking mass.

Since energy is conserved ΔE is also the loss of energy of the striking mass, giving the equation

$$\Delta E = E(1 - e^2) \quad \ldots\ldots [23]$$

Now $\Delta E/E$ can be eliminated from Equations [22] and [23] giving the coefficient e in terms of the function R, or

$$e = \frac{1 - R}{1 + R} \quad \ldots\ldots [24]$$

Using the theory developed in this paper, and assuming an expression for $\mathfrak{F}(\tau)$ satisfying the condition $\int_{t_0}^{t_1} \mathfrak{F}(\tau)d\tau = 1$, R can be determined. This gives directly the coefficient e, the rebound velocity ev_0, and the energy absorbed by the beam.

The remaining requirement is some indication for a suitable choice of $\mathfrak{F}(\tau)$, which must approximate to the actual normalized contact force. Information in this direction can be obtained from the known Hertz (3) solution for impact of the striking mass on the same beam, constrained so that it cannot vibrate. The corresponding normalized force variation $\mathfrak{F}_H(\tau)$ can be calculated directly. Although the vibration of the beam does produce some change in the normalized contact force, the Hertz solution would afford a reasonable approximation for application in the energy solution. It is not convenient to use $\mathfrak{F}_H(\tau)$ directly, however, since its form is such that the integral for R in Equation [21] could not be obtained. To overcome this difficulty, a simple force function is used which is chosen to conform approximately

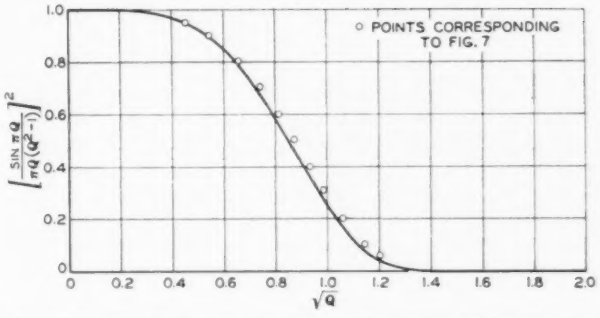

FIG. 6 ENERGY-DISTRIBUTION CURVE COMPARED WITH RESULTS FROM FIG. 7

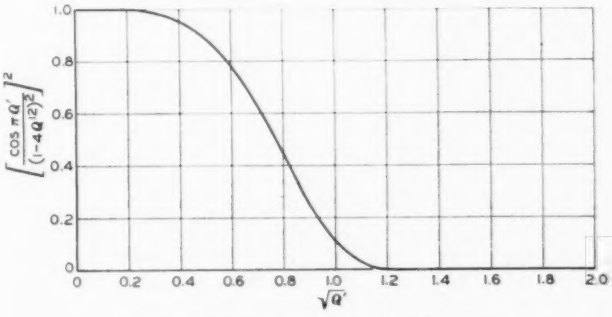

FIG. 7 ENERGY-DISTRIBUTION CURVE

to the Hertz variation $\mathfrak{F}_H(\tau)$. The function adopted by Zener and Feshbach(10) is

$$\mathfrak{F}_1(\tau) = \left(1 + \cos\frac{2\pi\tau}{T}\right)\Big/T$$

for $-T/2 \leq \tau \leq T/2$, and

$$\mathfrak{F}_1(\tau) = 0$$

for $|\tau| > T/2$.

The parameter T is chosen so that $\mathfrak{F}_1(\tau)$ has the same maximum ordinate as $\mathfrak{F}_H(\tau)$. This condition gives $T = 1.0873T_H$, where T_H is the time of contact of the Hertz impact. Substituting $\mathfrak{F}_1(\tau)$ in Equation [21] leads to a comparatively simple expression

$$R = \frac{m}{M}\sum_{n=1,3,5,}^{\infty}\left[\frac{\sin(\pi Q_n)}{\pi Q_n(Q_n^2 - 1)}\right]^2 \quad \ldots\ldots [25]$$

in which Q_n is a nondimensional quantity equal to $(\omega_n/2\pi)T$. The term Q_n has a simple physical significance; it is the number of oscillations of the nth mode of vibration in the time T. In Fig. 6 $\left[\frac{\sin(\pi Q_n)}{\pi Q_n(Q_n^2 - 1)}\right]^2$ is plotted against $\sqrt{Q_n}$ for use in solving specific impact problems.

For a beam simply supported at its ends, $\omega_n = n^2\omega_1$; therefore, the corresponding $Q_n = n^2Q_1$. Equation [25] becomes

$$R = \frac{m}{M}\sum_{n=1,3,5,}^{\infty}\left[\frac{\sin(\pi n^2Q_1)}{\pi n^2Q_1(n^4Q_1^2 - 1)}\right]^2 \quad \ldots\ldots [26]$$

It can be shown that in the limit as $Q_1 \to 0$, $R \to \infty$ as $Q_1^{-1/2}$, so that it is convenient to write

$$R = \frac{m}{MQ_1^{1/2}}G(Q_1) \quad \ldots\ldots [27]$$

TABLE 1 REBOUND VELOCITIES AFTER THE FIRST IMPACT, CALCULATED BY DIFFERENT METHODS

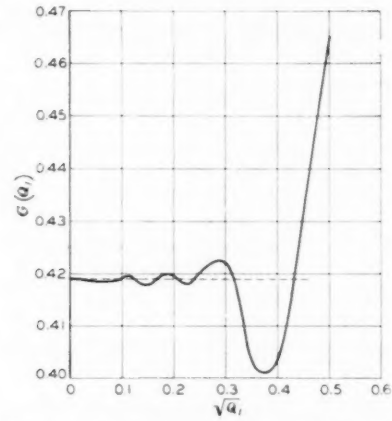

FIG. 8 VARIATION OF THE FUNCTION $G(Q_1)$

Now $G(Q_1)$ remains finite for all values of Q_1 and its variation is plotted against $\sqrt{Q_1}$ in Fig. 8.

The determination of rebound velocity and energy absorbed by the beam for a specific problem is thus made very simple; T_H is first obtained (12) giving immediately T and Q_1. The value of $G(Q_1)$ is ascertained using Fig. 8 giving R using Equation [27] and e from Equation [24].

In order to have some check on the validity of the assumed normalized force, an identical development has been evolved using the function

$$\mathfrak{F}_2(\tau) = \frac{\pi}{2T'} \cos \frac{\pi\tau}{T'}$$

for $-T'/2 \leq \tau \leq T'/2$, and

$$\mathfrak{F}_2(\tau) = 0$$

for $|\tau| > T'/2$.

Again T' is chosen so that the maximum ordinate of $\mathfrak{F}_2(\tau)$ equals that of $\mathfrak{F}_H(\tau)$. This condition gives $T' = 0.855\ T_H$. The integration for R is again quite simple giving

$$R = \frac{m}{M} \sum_{n=1,3,5}^{\infty} \left[\frac{\cos \pi Q_n'}{1 - 4Q_n'^2} \right]^2 \quad \ldots\ldots\ldots [28]$$

where $Q_n' = (\omega_n/2\pi)T'$, and is the number of oscillations of the nth mode in the time T'. Then $\left[\frac{\cos \pi Q_n'}{1 - 4Q_n'^2} \right]^2$ is plotted against $\sqrt{Q_n'}$ in Fig. 7. The difference between the curves in Figs. 6 and 7 is more apparent than actual when it is realized that the abscissas are different expressions in terms of T_H, the fundamental quantity defining this property of the impact. Transferring points from the curve in Fig. 7 to Fig. 6, using abscissas $\sqrt{Q}$ corresponding to the same value of T_H (the ordinate for $\sqrt{Q'}$ in Fig. 7 is plotted against $\sqrt{Q}$ in Fig. 6 using the relation $Q'/0.855 = T_H = Q/1.0873$), the individual points plotted in Fig. 6 are obtained which lie close to the curve. This procedure shows that the marked difference between the two force variations chosen has little effect on the energy absorbed by the beam.

As for the first force variation, the second one leads to the expressions

$$R = \frac{m}{M} \sum_{n=1,3,5}^{\infty} \left[\frac{\cos \pi n^2 Q_1'}{1 - 4n^4 Q_1'^2} \right]^2 \quad \ldots\ldots\ldots [29]$$

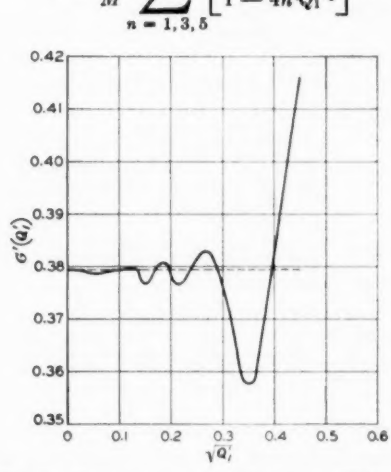

FIG. 9 VARIATION OF THE FUNCTION $G'(Q_1')$

For convenience, R is expressed in the form

$$R = \frac{m}{M(Q_1')^{1/2}} G'(Q_1') \quad \ldots\ldots\ldots [30]$$

where $G'(Q_1')$ is plotted against $\sqrt{Q_1'}$ in Fig. 9. The method of solving a particular problem using this curve is the same as that explained using the function $G(Q)$.

Table 1 gives values of the rebound velocity after the first impact, calculated by different methods for five specific problems enumerated in the first column.

Column I contains values of rebound velocity obtained using the reliable but tedious small-increment method.

Column II gives values obtained using the energy method described in this paper, assuming $\mathfrak{F}_1(\tau)$.

Column IV assumes the second form of force variation $\mathfrak{F}_2(\tau)$.

Columns III and V assume load variations similar to $\mathfrak{F}_1(\tau)$ and $\mathfrak{F}_2(\tau)$, respectively, based on a solution similar to Hertz's solution, but containing some allowance for the vibration of the beam. The development of this modified Hertz solution is given in Appendix 2. The only change which is thus introduced in the method described herein is that T and T' are calculated from T_{MH} (the contact duration for the modified Hertz solution) instead of using T_H, i.e., $T = 1.0873\ T_{MH}$, and $T' = 0.855\ T_{MH}$.

Column VI gives the average of the values in columns III and IV, and in all the cases considered shows excellent agreement

with the velocities in column I. This mean rebound velocity seems to give the most reliable approximate value yet obtained.

The errors shown by the differences between values of the rebound velocity obtained in different ways should be considered in terms of the change of velocity rather than the absolute value. For example, in the first problem tabulated, the sphere is brought almost to rest, and errors introduced are errors in the total change in momentum, i.e., on a basis of 12 fps, and not on a basis of the absolute value of the rebound velocity.

It has been shown that a reliable value for the rebound velocity (and so the coefficient e) is given by the energy method. This leads directly to a determination of the energy absorbed by the modes of vibration of the beam which is considered in the following section of this paper.

The Energy Spectrum and Its Significance

Equation [20] shows the amount of energy absorbed in each mode of vibration of a beam after impact. This expression leads to a direct determination of the energy spectrum of the beam, giving the distribution of the total vibrational energy among the separate modes. It further produces a criterion for impacts in which the vibrational energy is stimulated mainly in the fundamental mode of vibration. As was shown previously in this paper, such impacts can be dealt with satisfactorily by the approximate method described, although the method itself gives no indication whether this assumption is valid for a particular problem. Thus, using the energy method developed just previously, the group of problems to which the approximate solution is applicable can be determined. For this restricted group of impact problems the approximate solution is reliable for the contact duration and contact force. The impact force derived directly from the energy method, $F(\tau) = mv_0(1 + e)\mathfrak{F}_1(\tau)$ or $mv_0(1 + e)\mathfrak{F}_1(\tau)$ cannot be used as an approximation since it may differ appreciably from the correct value, although it gives excellent results for the subsequent motion.

Substituting $\mathfrak{F}_1(\tau)$ for $\mathfrak{F}(\tau)$ in Equation [20]

$$\Delta E_n = E\frac{m}{M}(1 + e)^2\left[\frac{\sin(\pi Q_n)}{\pi Q_n(Q_n^2 - 1)}\right]^2 \quad \ldots\ldots [31]$$

where $E(m/M)(1 + e)^2$ is independent of n, so that the distribution of energy among the modes is proportional to the value of $\left[\frac{\sin(\pi Q_n)}{\pi Q_n(Q_n^2 - 1)}\right]^2$. This can be taken directly from Fig. 6 by measuring the ordinates corresponding to the values of $\sqrt{Q_n}$, i.e., $n\sqrt{Q_1}$, $n = 1, 3, 5$, etc. Fig. 6 is therefore the energy spectrum for the beam, the ratio of the energies in the modes being proportional to the ordinates for $\sqrt{Q}$ equal to $\sqrt{Q_1}$, $3\sqrt{Q_1}$, $5\sqrt{Q_1}$, etc.

This investigation explains the apparent inconsistencies in the application of the approximate solution. The value of $\sqrt{Q_1}$ for the example corresponding to Fig. 4 is 0.434. Fig. 6 shows that the energy is distributed in the proportion 0.956 : 0.012 : 0.00 . . . , between the first, third, etc., modes. Thus, the energy is absorbed almost entirely by the fundamental mode of vibration, and replacing the beam by a system with one degree of freedom is justified. In this case, as shown in Fig. 4, the approximate solution shows good agreement.

The example corresponding to Fig. 5 has $\sqrt{Q_1} = 0.1729$. Fig. 6 gives the distribution of energy between the first few odd modes to be proportional to 1.00 : 0.908 : 0.470 : 0.040 : 0.00, so that to replace the beam by a system of one degree of freedom would be expected to produce appreciably different conditions for the impact. This is shown to be the case in Fig. 5, in which the force variations for the beam and corresponding one-degree-of-freedom system are different, both being calculated by the small-increment method. The approximate solution shows excellent agreement with the force variation for the one-degree-of-freedom spring system which is, however, useless as an approximation to the beam-impact problem.

It appears that the approximate method supplies a simple reliable solution for the group of problems in which energy is absorbed mainly in the fundamental mode of vibration of the beam. This is to be expected, for when this is true, the beam behaves like a one-degree-of-freedom system. A limited amount of energy in the third mode does not affect the force variation appreciably, since central deflection and not energy is the determining factor ($kF^{2/3} = \alpha = \delta - \eta$). The minimum value of $\sqrt{Q_1}$ to give reasonable results is about 0.3.

The assumption that the impact duration is short compared with the period of the fundamental mode of the beam also restricts the range of Q_1 for which the approximate method gives reliable results. From this point of view small values of Q_1 give the best approximation. The limit for which a good approximation can be expected is $Q_1 = 0.25$, $\sqrt{Q_1} = 0.5$. Though toward the end of the impact, $Q_1 = 0.25$ will lead to quite large values of $\omega_1 t$, this is not important since toward the end of impact the contact force is small, producing little effect on the final motion. Therefore, the approximate method is useful for values of $\sqrt{Q_1}$ between 0.3 and 0.5, and it is in this range that many practical problems lie. Values of $\sqrt{Q_1} > 0.5$ are unusual, so that the most frequent obstacle to the application of this approximate method is that the vibrational energy is not sufficiently concentrated in the fundamental mode. This leads to a very important criticism of Lennertz' paper (9), since he considered the validity of the short contact assumption only, and merely stated, without investigation, that the equivalence of a one-degree-of-freedom system was satisfactory.

Motion of the Striking Mass and of the Beam After Impact

The solution of impact problems based on energy considerations leads to an expression for the free vibration of the beam after contact has ceased. The displacement-time curves for the center of the beam and for the mass can be drawn, from which the existence of a repeated impact can be determined.

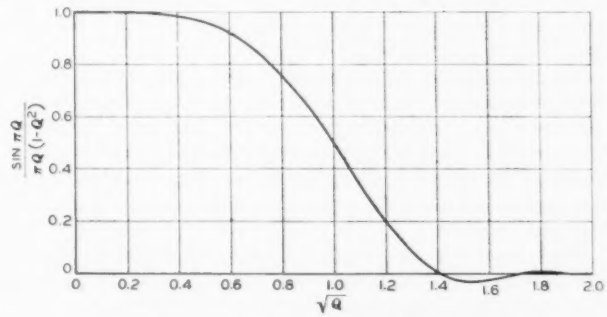

Fig. 10 Graph of Displacement Function

Equation [15] is directly integrable assuming the normalized force variation $\mathfrak{F}_n(\tau)$, giving

$$C_n(t) = \sqrt{\frac{2}{l}}\frac{(-1)^{\frac{n-1}{2}}}{\omega_n q} mv_0(1 + e)\frac{\sin(\pi Q_n)}{\pi Q_n(1 - Q_n^2)}\sin(\omega_n t). \quad [32]$$

$$n = 1, 3, 5 \ldots$$

Using Equation [13], the central deflection due to the nth mode is

$$C_n(t)\sqrt{\frac{2}{l}}\sin\left(\frac{n\pi}{2}\right) = \frac{m}{M}\frac{v_0(1 + e)}{\omega_n}\frac{\sin(\pi Q_n)}{\pi Q_n(1 - Q_n^2)}\sin(\omega_n t) \ldots [33]$$

where $n = 1, 3, 5 \ldots\ldots$, $\omega_n = n^2\omega_1$, and $Q_n = n^2 Q_1$.

The motion of the center of the beam is thus composed of the

superposition of sinusoidal oscillations given by Equation [33]. Their amplitudes decrease rapidly with increasing n, so that normally all but the first two or three modes of vibration remain quiescent. To simplify the determination of the deflection, $\sin(\pi Q/\pi)Q(1-Q^2)$ is plotted against $\sqrt{Q}$ in Fig. 10.

In solving a specific problem, $\sqrt{Q_1}$ and e are calculated as shown previously, the value of $\sin(\pi Q_n)/\pi Q_n(1-Q_n^2)$ being then given as the ordinate for $\sqrt{Q} = n\sqrt{Q_1}$ in Fig. 10. The vibration, both amplitude and phase, is given by substitution in Equation [33]. The sinusoidal displacement-time curves are plotted for each mode, and their superposition gives the motion of the center of the beam. The time origin is at the middle of the impact duration and Equation [33] is only valid after contact has ceased, since integrations were carried out for $t > T/2$. This

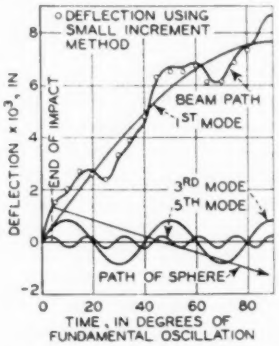

FIG. 11 COMPARISON OF DISPLACEMENTS OBTAINED BY DIFFERENT METHODS, AND REBOUND OF THE STRIKING MASS

explains the apparent inconsistency of zero deflection at the middle of the impact.

This procedure is applied to the problem corresponding to Fig. 5 ($m = 50$ lb, $M = 298.5$ lb, $\omega_1 = 531$ sec^{-1}, and $\sqrt{Q_1} = 0.1729$). The displacement so obtained is compared in Fig. 11 with values given by the small-increment method of solution. Excellent agreement is demonstrated.

The advantage of the displacement curve obtained from energy considerations (in addition to the comparison between a mere half hour's work, and two or three days' tedious ploughing through the small increment method) results, since the motion is already harmonically analyzed, which is more useful than a knowledge of the displacement at isolated time intervals as given by the small increment method.

The rebound of the striking mass is also shown in Fig. 11. The mass moves with constant velocity ev_0 from the position the beam had when contact ceased.

Intersection of the two displacement curves indicates a repeated impact. The statement made by Zener and Feshbach (10), "multiple collisions will occur whenever the calculated e is negative," is true but not necessary. Repeated impacts also occur when e is positive and the rebound velocity is not sufficient to carry the mass out of the range of the vibrating beam before a second impact occurs. Experimental evidence of this state of affairs appears in Tuzi and Nisida's (8) illustrations.

Using a method analogous to that adopted for the first impact, the second impact can be dealt with. Again, a normalized contact-force variation is assumed. The Hertz (3) force variation, calculated for a velocity of approach equal to the relative velocity between the beam and the mass, is used as a basis for the assumed variation $\mathfrak{F}_1(\tau)$, exactly as $\mathfrak{F}_1(\tau)$ was defined for the first impact in the energy method. The free vibration already present in the beam due to the first impact complicates the problem somewhat. We know $C_n(t) = A_n \sin \omega_n t$ are the generalized coordinates of the vibration already disturbing the beam due to the first impact. Defining e_1, a coefficient of restitution for the second impact, by writing $e_1(-ev_0)$ for the velocity of rebound,[7] energy and momentum considerations determine e_1 by the equation

$$(1-e_1) = (1+e_1)R + \frac{2}{(-ev_0)} \sum_{n=1,3,5}^{\infty} A_n\omega_n \sqrt{\frac{2}{l}} (-1)^{\frac{n-1}{2}} \frac{\sin(\pi Q_n)}{\pi Q_n(1-Q_n^2)} \cos(\omega_n t_m) \quad [34]$$

where t_m is the displacement in time between the two impacts, and R is defined in Equation [21].

It is interesting to note that in applying Equation [34] to the first impact $A_n = 0$, and the equation $e_1 = (1-R)/(1+R)$ is obtained which is the same as Equation [24].

When e_1 has been determined from Equation [34], the vibration superimposed on the beam due to the second impact can be calculated from Equation [32], replacing v_0 by $(-ev_0)$, and e by e_1. Adding the result to the vibration already present in the beam, the total motion is obtained.

Investigating the motion after the second impact, the existence of another impact can be decided. Repeated impacts can be studied using Equation [34] until the mass rebounds out of the region covered by the vibrating beam and the whole impact process is complete.

THE FORM OF THE DEFLECTION CURVE OF THE BEAM

The knowledge of the generalized coordinates $C_n(t)$ for the

[7] Here $-ev_0$ is the velocity of the mass between the first and second impacts; it is positive when in the same direction as v_0.

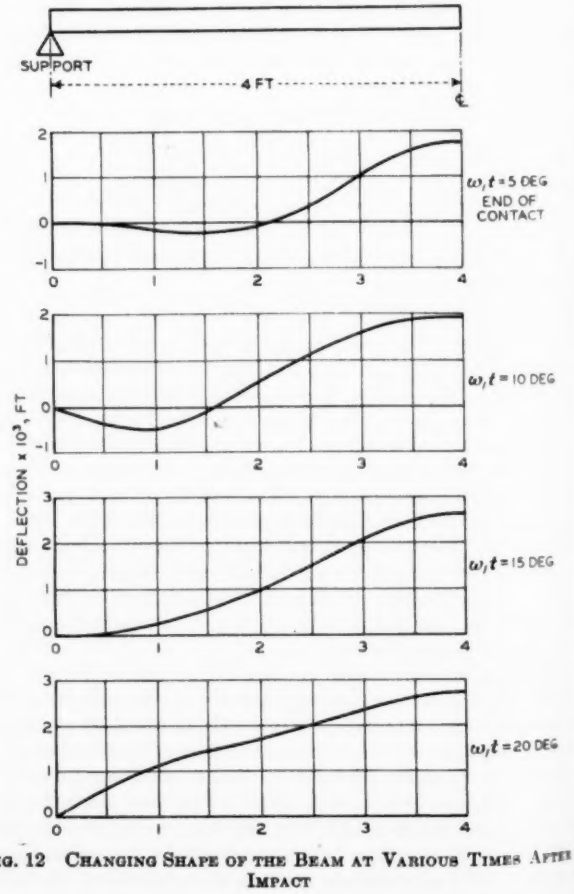

FIG. 12 CHANGING SHAPE OF THE BEAM AT VARIOUS TIMES AFTER IMPACT

vibration of the beam after impact leads directly to the changing deflection curve of the beam.

Equation [13] gives the motion of all points along the beam, and substituting for $C_n(t)$ from Equation [32], becomes

$$u(x,t) = \frac{m}{M} v_0(1+e) \sum_{n=1,3,5} \frac{(-1)^{\frac{n-1}{2}}}{\omega_n} \frac{\sin(\pi Q_n)}{\pi Q_n(1-Q_n^2)} \sin(\omega_n t) \sin\left(\frac{n\pi x}{l}\right) \quad [35]$$

This equation only holds after contact has ceased. The deflection curve of the beam is composed of the superposition of sine terms, the amplitudes of these Fourier terms changing with time. For any time t these amplitudes are given in Equation [33], and can be readily evaluated using Fig. 10 or from the central deflections considered in the last section.

Fig. 12 shows the changing shape of the beam due to the impact considered previously ($m = 50$ lb, $M = 298.5$ lb, $\omega_1 = 531$ sec^{-1}, and $\sqrt{Q_1} = 0.1729$). Immediately after contact has ceased the deflection is limited mainly to the central portion of the beam; near the supports the deflection is small and in the opposite direction. Later, the first mode of vibration dominates. The curves of Fig. 9 show a marked difference from the static-deflection curve for central loading, indicating that Cox's (13) assumption of static-deflection form is unjustified.

Beam-deflection curves, obtained for the impact of a 470-lb mass on the beam just considered, agree well with the experimental investigation carried out by Arnold (7) as interpreted by Smith in the discussion of Arnold's paper. He also obtains the initial negative deflection near the supports due to the third harmonic.

Conclusion

It has been shown that energy considerations lead to many characteristics of the impact process due to a mass striking a beam. For simplicity, this paper has dealt solely with central impact on a beam simply supported at its ends. No difficulties are encountered in generalizing the method for impact at any point along a beam which is supported in any way. A development, analogous to that already evolved, leads to similar conclusions, the relations being expressed in terms of the normalized characteristic functions for the modes of vibration. This general theory is developed briefly in Appendix 1, the procedure being identical with that adopted for the specialized problem.

Acknowledgments

The author wishes to express his appreciation to Professor S. Timoshenko for suggesting the subject and for valuable help offered by him in its development. The author is also grateful to the Commonwealth Fund whose Fellowship made the work possible.

Appendix 1

THE GENERALIZED IMPACT PROBLEM

The development carried out in the body of this paper for central impact on a uniform beam simply supported at its ends is briefly repeated here for a uniform beam with general supporting conditions, the impact occurring at any position along its length. Since the development is parallel to that for the special case already considered, little verbal explanation is given; the corresponding equations are denoted by the same reference number or letter which was used in the simpler development, but carry the suffix a for discussers' reference.

The vibration of the beam is considered in terms of the normalized characteristic functions $u_n(x)$ and the generalized coordinates $C_n(t)$ of the normal modes of vibration. The deflection of any point of the beam is given by

$$u(x,t) = \sum_{n=1,2,3,\ldots} u_n(x) C_n(t) \quad [13a]$$

The general integral equation for impact becomes

$$k[F(t)]^{3/2} = v_0 t - \frac{1}{m}\int_0^t F(\tau)(t-\tau)d\tau - \sum_{n=1,2,3} \frac{1}{M_n}\int_0^t F(\tau)\frac{\sin[\omega_n(t-\tau)]}{\omega_n} d\tau \quad [4a]$$

where the reduced mass of the beam for the nth mode $M_n = q/[u_n(c)]^2$, $x = c$ being the point of impact.

The approximate method remains unchanged, although the range of validity of the assumptions used differs. The introduction of the second mode of vibration, which was eliminated due to symmetry in the special problem dealt with before, makes the consideration of only the first mode a more restrictive assumption.

The concept of the normalized contact force is applicable to this generalized impact problem.

The vibrations produced in the beam due to a force variation $F(\tau)$, acting at the point $x = c$, are given by the differential equation

$$\frac{d^2C_n}{dt^2} + \omega_n^2 C_n^2 = \frac{1}{q} F(t) u_n(c) \quad [14a]$$

Assuming no motion at the time t_0 when the force commences to act

$$C_n(t) = \frac{u_n(c)}{\omega_n q}\int_{t_0}^t \sin[\omega_n(t-\tau)]F(\tau)d\tau \quad [15a]$$

giving the energy in each mode after contact has ceased

$$\Delta E_n = \frac{[u_n(c)]^2}{2q}\left|\int_{t_0}^{t_1} F(\tau)e^{i\omega_n\tau}d\tau\right|^2 \quad [17a]$$

Transferring to the normalized force variation $\mathfrak{F}(\tau) = F(\tau)/mv_0(1+e)$ Equation [17a] becomes

$$\Delta E_n = \frac{m^2v_0^2(1+e)^2}{2q}[u_n(c)]^2\left|\int_{t_0}^{t_1}\mathfrak{F}(\tau)e^{i\omega_n\tau}d\tau\right|^2 \quad [20a]$$

The coefficient of restitution, e, is given by

$$e = \frac{1-R}{1+R} \quad [24a]$$

where

$$R = \frac{m}{q}\sum_{n=1,2,3,\ldots}[u_n(c)]^2\left|\int_{t_0}^{t_1}\mathfrak{F}(\tau)e^{i\omega_n\tau}d\tau\right|^2 \quad [21a]$$

Assuming the normalized force variation $\mathfrak{F}_1(\tau)$

$$R = \frac{m}{q}\sum_{n=1,2,3,\ldots}[u_n(c)]^2\left[\frac{\sin(\pi Q_n)}{\pi Q_n(Q_n^2-1)}\right]^2 \quad [25a]$$

For any particular problem R can be calculated using Fig. 6.

This gives e from Equation [24a], in terms of which the energy distribution after contact is expressed as

$$\Delta E_n = E\frac{m}{q}(1+e)^2[u_n(c)]^2\left[\frac{\sin(\pi Q_n)}{\pi Q_n(Q_n^2-1)}\right]^2 \ldots [31a]$$

Using Fig. 6, Equation [31a] gives the energy distribution between the modes of vibration of the beam.

The motion after contact is given by

$$u(x,t) = \sum_{n=1,2,3,\ldots}^{\infty} C_n(t)u_n(x) =$$

$$\frac{mv_0(1+e)}{q}\sum_{n=1,2,3,\ldots}^{\infty}\frac{u_n(c)}{\omega_n}\frac{\sin(\pi Q_n)}{\pi Q_n(1-Q_n^2)}\sin(\omega_n t)\cdot u_n(x) \ldots [35a]$$

This equation includes the motion of the point of contact of the beam, leading to a study of the subsequent impact procedure. Equation [35a] also gives the deflection form of the beam when contact has ceased.

The energy-distribution condition for the validity of the approximate method can be studied using Equation [31a], which gives the energy spectrum for the beam. The appearance of the second harmonic will make the restriction that the energy is absorbed mainly in the fundamental mode more stringent, and special care is needed to insure that the assumptions are valid when this approximate method is used.

This theory developed for impact on a beam can be extended to impact on plates, the plate deflections being expressed in terms of the characteristic functions for the normal modes of vibration. Since, in the case of plate vibrations, the natural frequencies of the normal modes are closer to the fundamental than for beams, special care must be taken in considering the validity of the approximations used for the approximate method.

Appendix 2

A MODIFIED HERTZ SOLUTION

This approximate solution has been developed as a basis from which an approximation for the normalized contact force variation can be derived. It gives a better approximation to the correct contact force than the Hertz (3) solution, since it contains some allowance for the effect of the vibrating beam, whereas the Hertz solution applies to impact of a mass on a beam constrained so that it cannot vibrate.

The fundamental mode of vibration only is considered and the duration of contact is assumed small compared with the period of the fundamental. The second assumption enables $\sin\omega_1(t-\tau)$ to be replaced by $\omega_1(t-\tau)$ and Equation [4] becomes

$$k[F(t)]^{3/2} = v_0 t - \frac{1}{m}\int_0^t F(\tau)(t-\tau)d\tau - \frac{1}{M}\int_0^t F(\tau)(t-\tau)d\tau \ldots [37]$$

Combining the last two terms and writing $\frac{1}{M_e} = \frac{1}{m} + \frac{1}{M}$, this equation reduces to the Hertz equation for a mass M_e striking the constrained beam with a velocity v_0. The corresponding force variation is given by Hertz's formula and is termed the "modified Hertz solution."

Analysis of Clamped Rectangular Plates

By DANA YOUNG,[1] STORRS, CONN.

This paper attempts to solve the problem of the bending action of rectangular plates clamped at all four edges and subjected to lateral loading. Analytical in nature, the author's investigation is based upon the ordinary theory of bending of thin plates as treated in Lagrange's equation of the middle surface. The superposition method is used and applied to a number of loadings not hitherto studied.

THE bending of rectangular plates which are clamped at all four edges and subjected to the action of lateral loads is a problem which has received considerable attention because of its technical importance. Two main methods of attack have been used for obtaining solutions, namely, (*a*) Ritz's energy method (1),[2] a recent discussion of which has been given by G. Pickett (2), and (*b*) the superposition method proposed by S. P. Timoshenko (3) as a generalization of Hencky's solution (4). These methods are approximate in the rigorous mathematical sense but, practically, the results may be obtained to any desired degree of accuracy by taking sufficient terms in the infinite series of simultaneous equations which occur in both these methods. To date, complete analyses are available only for the case of a uniform load and for the case of a central concentrated load. In this paper, Timoshenko's method is applied to a number of loadings which have not been treated before. Consideration is given first to symmetrically placed loads and to antisymmetrical loadings. Then unsymmetrically distributed loads are obtained by superposition of the preceding cases. The numerical calculations have been carried out for several loadings and values for the deflections, moments, and shears at critical points are given.

This is an analytical investigation based upon the ordinary theory of bending of thin plates, as governed by Lagrange's equation of the middle surface. Discussion of this theory, derivation of the differential equation, and the relations for moments and shears are available in references such as (5) and (6), and will not be given here. For the plates treated in this paper it is assumed that all four edges are perfectly fixed so there is no deflection or change in slope at the edges under the action of the lateral loads.

Nomenclature

The following nomenclature is used in the paper:

- a = length of plate in x direction
- b = length of plate in y direction
- h = thickness of plate (assumed constant in this investigation)
- E = modulus of elasticity of plate material
- ν = Poisson's ratio (assumed equal to 0.3 in numerical calculations)
- D = $Eh^3/12(1 - \nu^2)$ flexural rigidity of plate
- M_x, M_y = bending moments per unit length of plate on sections perpendicular to x and y axes, respectively, taken as positive when producing compression at top of plate
- $(M)_{ss}$ = bending moment for a simply supported plate carrying the load under consideration
- Q_x, Q_y = vertical shearing forces per unit length of plate on sections perpendicular to the x and y axes, respectively, taken as positive on a rectangular element of plate when acting upward on the side of the element having the smaller value of x or y, respectively.
- w = deflection of plate at any point, assumed positive downward
- P = concentrated load, assumed positive when acting downward
- q = intensity of a distributed lateral load, assumed positive when acting downward
- p = intensity of a triangularly distributed load at unit distance from line of zero load
- x, y = rectangular coordinates in plane of middle surface of plate. For convenience in discussion, the plane of the plate will be assumed horizontal and loads will then be acting vertically. The origin of coordinates is taken at center of plate
- k, m = integers, with values as indicated on the summation sign where they occur
- A, B, G, H = coefficients which are defined where used

$$\alpha_m = \frac{m\pi b}{2a} \qquad \delta_m = \frac{m\pi a}{b}$$

Symmetrical Loadings

A symmetrical load is one which is symmetrically distributed about each of the coordinate axes through the center of the plate. The general method for analyzing clamped rectangular plates under such loadings has been given by Timoshenko (3). Detailed results for a uniformly loaded plate have been worked out by I. A. Wojtaszak (7) and T. H. Evans (8). Calculations for a central concentrated load have also been given (9). Deflections, moments, and shears for uniformly loaded plates of several proportions are summarized in Table 1 for later use. These results were taken from Wojtaszak's paper with some additional values computed by the author.

Antisymmetrical Loads

The term "antisymmetrical" is used to designate load distributions which have equal but opposite intensities at corresponding positive and negative values of the coordinates of one axis. The loading is assumed symmetrically distributed parallel to the other axis. In the following work the loads are taken as antisymmetrically distributed about the x axis and symmetrically distributed about the y axis, so that $q(x, y_1) = -q(x, -y_1)$ and $q(x_1, y) = q(-x_1, y)$. These loadings are not of practical interest by themselves, but are for use in combination with symmetrical loads to obtain cases of unsymmetrical loadings. Since Timoshenko's method has not been previously carried through in detail for this type of loading, it appears worth-while to develop here the necessary equations.

The problem is to find a solution of the differential equation of the middle surface of a bent plate

$$\frac{\partial^4 w}{\partial x^4} + 2\frac{\partial^4 w}{\partial x^2 \partial y^2} + \frac{\partial^4 w}{\partial y^4} = \frac{q}{D}$$

Presented at the Annual Meeting, New York, N. Y., December 2–6, 1940, of The American Society of Mechanical Engineers.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 10, 1941, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

that will satisfy the boundary conditions for clamped edges

$$(w)_{x=\pm a/2} = (w)_{y=\pm b/2} = 0\,, \quad \left(\frac{\partial w}{\partial x}\right)_{x=\pm a/2} = \left(\frac{\partial w}{\partial y}\right)_{y=\pm b/2} = 0$$

This may be done by taking w as the sum of three solutions

$$w = w_1 + w_2 + w_3 \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

For the function w_1 we take the solution for a simply supported plate carrying the given antisymmetrical lateral load. In most cases this is readily derived using known methods. For w_2 we take the solution for a simply supported plate with symmetrically distributed edge moments applied at $y = {}^1/_2 b$, and equal but opposite moments applied at $y = -{}^1/_2 b$. It is convenient to take these moments in the form of a cosine series

$$(M_y)_{y=b/2} = -(M_y)_{y=-b/2} = \sum_{m=1,3,5,\ldots} A_m(-1)^{(m-1)/2} \cos\frac{m\pi x}{a} \ldots [2]$$

and then the function w_2 is given by

$$w_2 = \frac{a^2}{2\pi^2 D}\sum_{m=1,3,5\ldots}\frac{A_m(-1)^{(m-1)/2}}{m^2\sinh\alpha_m}\left(\alpha_m\coth\alpha_m\sinh\frac{m\pi y}{a} - \frac{m\pi y}{a}\cosh\frac{m\pi y}{a}\right)\cos\frac{m\pi x}{a} \ldots [3]$$

For w_3 we take the solution for a simply supported plate with antisymmetrically distributed edge moments of the form

$$(M_x)_{x=\pm a/2} = \sum_{m=1}^{\infty} B_m \sin\frac{2m\pi y}{b} \ldots\ldots\ldots [4]$$

applied along the edges $x = \pm {}^1/_2 a$. The deflection function for this case is given by

$$w_3 = \frac{b^2}{8\pi^2 D}\sum_{m=1}^{\infty}\frac{B_m}{m^2\cosh\delta_m}\left(\delta_m\tanh\delta_m\cosh\frac{2m\pi x}{b} - \frac{2m\pi x}{b}\sinh\frac{2m\pi x}{b}\right)\sin\frac{2m\pi y}{b} \ldots [5]$$

The coefficients A_m and B_m in the preceding equations are to be determined from the condition that the slope at the boundaries is zero. Thus, taking $\left(\frac{\partial w}{\partial y}\right)_{y=b/2} = 0$ and expressing the terms containing $\cosh\frac{2m\pi x}{b}$ and $\frac{2m\pi x}{b}\sinh\frac{2m\pi x}{b}$ by a cosine series, we obtain

$$\left(\frac{\partial w}{\partial y}\right)_{y=b/2} = \left(\frac{\partial w_1}{\partial y}\right)_{y=b/2} + \frac{a}{2\pi D}\sum_{m=1,3,5,\ldots} A_m\frac{(-1)^{(m-1)/2}}{m}\left(\frac{\alpha_m}{\sinh^2\alpha_m} - \coth\alpha_m\right)\cos\frac{m\pi x}{a} + \frac{8a^2}{\pi^2 bD}\sum_{m=1}^{\infty}\frac{B_m(-1)^m}{m^3} - \sum_{k=1,3,5,\ldots}\frac{k(-1)^{(k-1)/2}}{\left(\frac{4a^2}{b^2}+\frac{k^2}{m^2}\right)^2}\cos\frac{k\pi x}{a} = 0 \ldots [6]$$

Since this relation holds for any cosine term, say $\cos\frac{k\pi x}{a}$, the summation signs may be dropped and the cosine term canceled, thus giving

$$A_k\left[\coth\alpha_k - \frac{\alpha_k}{\sinh^2\alpha_k}\right] - \frac{k^2b^2}{\pi a^2}\sum_{m=1}^{\infty}\frac{m(-1)^m B_m}{\left(m^2+\frac{k^2b^2}{4a^2}\right)^2} = \frac{2\pi Dk(-1)^{(k-1)/2}}{a}G_k \ldots [7]$$

where G_k is found by expressing the slope at $y = {}^1/_2 b$ due to w_1 in a cosine series of the form

$$\left(\frac{\partial w_1}{\partial y}\right)_{y=b/2} = \sum_{k=1,3,5,\ldots} G_k\cos\frac{k\pi x}{a} \ldots\ldots [8]$$

One equation in the unknowns A_k and B_m is obtained for each value of $k = 1, 3, 5, \ldots$, substituted in Equation [7].

Similarly, for zero slope at $x = {}^1/_2 a$ we find the expression

$$-B_m(-1)^m\left[\tanh\delta_m + \frac{\delta_m}{\cosh^2\delta_m}\right] + \frac{32m^2a^3}{\pi b^3}\sum_{k=1,3,5\ldots}\frac{kA_k}{\left(k^2+\frac{4m^2a^2}{b^2}\right)^2} = -\frac{4\pi m(-1)^m D}{b}H_m \ldots [9]$$

where H_m is obtained by expressing the slope at $x = {}^1/_2 a$ due to w_1 in a sine series of the form

$$\left(\frac{\partial w_1}{\partial x}\right)_{x=a/2} = \sum_{m=1}^{\infty} H_m\sin\frac{2m\pi y}{b} \ldots\ldots [10]$$

From Equation [9] we obtain one equation in the unknown coefficients A_k and B_m for each value of $m = 1, 2, 3, 4 \ldots\ldots$

Equations [7] and [9] lead to a double-infinite series of simultaneous equations in the unknowns A_k and B_m, which may be solved approximately by assuming that terms higher than a given order may be neglected. In general, it was found most expeditious to solve this system of equations by successive approximations as illustrated in (3, 7, 8). The left-hand members of these equations are independent of the load and depend only upon the ratio b/a of the length of the sides, so that once the numerical values of these terms are computed for a plate of given proportion, they may be used for any loading.

The numerical calculation of the coefficients A_k and B_m completes the solution of Equation [1]. Values of the deflection, moments, and shears at any point may then be determined from the known relations in the theory of plates. Detailed solutions for two particular antisymmetrical loadings will now be given.

Triangular Load Distribution.

The load intensity in this case varies linearly from the x axis to the edges $y = \pm {}^1/_2 b$ as shown in Fig. 1. The intensity at any point is given by the expression $q = py$, where p is the intensity at unit distance from the x axis. It is easily verified that the deflection of a simply supported plate carrying this loading is given by

$$w_1 = \frac{pa^4}{\pi^5 D}\sum_{m=1,3,5\ldots}\frac{(-1)^{(m-1)/2}}{m^5}\left[4y - \frac{b(2+\alpha_m\coth\alpha_m)}{\sinh\alpha_m}\sinh\frac{m\pi y}{a} + \frac{b}{\sinh\alpha_m}\times\frac{m\pi y}{a}\times\cosh\frac{m\pi y}{a}\right]\cos\frac{m\pi x}{a} \ldots [11]$$

An alternate expression for w_1 which is useful for determining the load coefficient H_m, is as follows

$$w_1 = \frac{pb^5}{16\pi^5 D}\sum_{m=1}^{\infty}\frac{(-1)^m}{m^5}\left[-1 + \frac{{}^1/_2\delta_m\tanh\delta_m + 1}{\cosh\delta_m}\cosh\frac{2m\pi x}{b} - \frac{1}{2\cosh\delta_m}\times\frac{2m\pi x}{b}\times\sinh\frac{2m\pi x}{b}\right]\sin\frac{2m\pi y}{b} \ldots [12]$$

From these two equations we find

$$G_k = \frac{pa^4(-1)^{(k-1)/2}}{\pi^4 k^4 D}\left[\frac{4}{\pi k} - \frac{b}{a}\left(\frac{\alpha_k}{\sinh^2 \alpha_k} + \coth \alpha_k\right)\right] \quad [13]$$

$$H_m = \frac{pb^4(-1)^m}{16\pi^4 m^4 D}\left[\tanh \delta_m - \frac{\delta_m}{\cosh^2 \delta_m}\right] \quad [14]$$

Substituting these expressions for G_k and H_m into Equations [7] and [9], we obtain the system of equations from which the coefficients A_k and B_m may be calculated. This has been done for several different ratios b/a of the length of the sides and the results are given in Table 2. Using these values, deflections, moments, and shears have been calculated for various critical points and these are given in the same table.

Uniform Load in Opposite Directions on Each Half of Plate.

This loading is shown in Fig. 2. There is a uniform load of intensity q in the region $y > 0$, and a uniform load of intensity $-q$ in the region $y < 0$. The deflection for a simply supported plate carrying this load may be expressed as

$$w_1 = \frac{2pa^4}{\pi^5 D}\sum_{m=1,3,5\ldots}\frac{(-1)^{(m-1)/2}}{m^5}\left[2 - 2\cosh\frac{m\pi y}{a} + \frac{m\pi y}{a}\sinh\frac{m\pi y}{a} + \frac{1}{\sinh^2 \alpha_m}(\alpha_m - \alpha_m \cosh \alpha_m - 2\sinh \alpha_m + 2\sinh \alpha_m \cosh \alpha_m)\sinh\frac{m\pi y}{a} + \frac{1 - \cosh \alpha_m}{\sinh \alpha_m} \times \frac{m\pi y}{a} \times \cosh\frac{m\pi y}{a}\right]\cos\frac{m\pi x}{a} \quad [15]$$

which is valid only in the region $y > 0$. An alternate expression for w_1 which is useful in the determination of H_m is

$$w_1 = \frac{pb^4}{8\pi^5 D}\sum_{m=1,3,5\ldots}\frac{1}{m^5}\left[2 - \frac{2 + \delta_m \tanh \delta_m}{\cosh \delta_m}\cosh\frac{2m\pi x}{b} + \frac{2m\pi x}{b\cosh \delta_m}\sinh\frac{2m\pi x}{b}\right]\sin\frac{2m\pi y}{b} \quad [16]$$

From these two equations the load coefficients are found to be

$$G_k = -\frac{2pa^3(-1)^{(k-1)/2}}{\pi^4 k^4 D}\left[\tanh\frac{\alpha_k}{2} - \frac{\frac{1}{2}\alpha_k}{\cosh^2\frac{\alpha_k}{2}}\right] \quad [17]$$

$$H_m = -\frac{pb^3}{4\pi^4 m^4 D}\left[\tanh \delta_m - \frac{\delta_m}{\cosh^2 \delta_m}\right] \text{ for } m = 1, 3, 5 \ldots . \quad [18]$$

$$H_m = 0 \text{ for } m = 2, 4, 6 \ldots .$$

The results calculated for this case are given in Table 3.

Unsymmetrical Loadings

Solutions for loads which are unsymmetrically distributed about one of the coordinate axes (here taken as the x axis) may be readily obtained by superposing solutions for symmetrical and antisymmetrical loadings.

Triangular (Hydrostatic) Loading.

Let q_0 be the maximum intensity of loading for this case which is shown in Fig. 3. The solution for this load is obtained by superposition of the solutions for a uniform load of intensity $\frac{1}{2}q_0$ and for an antisymmetrical triangular loading of intensity $q = (q_0/b)y$. Results for these two component loadings are given in Tables 1 and 2. Combining these in the manner specified, we obtain the deflections, moments, and shears for the hydrostatic loadings. The values for this case are summarized in Table 4.

Trapezoidal Load Distribution.

For this case which is shown in Fig. 4, the load intensity varies linearly from a minimum value q_2 at $y = -\frac{1}{2}b$, to a maximum q_1 at $y = \frac{1}{2}b$. The average intensity is $q_a = \frac{1}{2}(q_1 + q_2)$ and the increase in load intensity per unit length is $p = q_b/b$ where $q_b = q_1 - q_2$. The results for this case are then found by superposition of the results for a uniform load of intensity q_a and the results for an antisymmetrical triangular load of intensity $q = (q_b/b)y$.

Uniform Load Over Half the Plate.

For this loading which is shown in Fig. 5, there is a uniform load of intensity q_0 over the region $y > 0$, but no load whatsoever in the region $y < 0$. This loading is obtained by superposition of a uniform load of $\frac{1}{2}q_0$ over the entire plate and of an antisymmetrical uniform load of intensity $\frac{1}{2}q_0$ in opposite directions on each half of the plate. Results for the two component loadings may be found in Tables 1 and 3. The deflections and moments for the unsymmetrical load are then as given in Table 5.

Noncentral Concentrated Load.

A plate with a concentrated load P at a point $x = u$, $y = 0$, as shown in Fig. 8, can be handled by superposition of the symmetrical case shown in Fig. 6, and the antisymmetrical case shown in Fig. 7. Solutions for these later two loadings may be carried through by the methods described. As an example, the particular case of a square plate with load P at the quarter point, i.e., $u = \frac{1}{4}b$, has been worked out and the results given in Table 6.

As is well known, in the ordinary theory of bending of plates, the moments under a concentrated load become infinite unless consideration is given to the area over which the load is distributed. This has been discussed by Timoshenko (10) for a simply supported rectangular plate and he has given expressions for this moment in terms of the area over which the load is distributed. Call this moment $(M)_{ss}$. Then for a clamped plate, the moment at the concentrated load may be written as $(M)_{ss} - M_{2,3}$, where $M_{2,3}$ is the moment at the load due the functions w_2 and w_3. In Table 6 the moments at the concentrated load are thus expressed.

The Orthogonally Stiffened Plate Under Uniform Lateral Load

By HENRY A. SCHADE,[1] WASHINGTON, D. C.

The problem of designing structures with orthogonally stiffened plates under lateral loading has been solved approximately by the infinite-strip method and has been applied, for example, to the double-bottom structure of a ship. Under certain conditions where the side ratio, that is, the ratio of the longitudinal dimension to the transverse dimension, is small, the approximate solution is inadequate. The author gives herein an exact solution applicable to all side ratios.

THE problem here discussed may be described as follows: A rectangular grid of orthogonally intersecting beams rests on rigid supports on all four edges, as shown in Fig. 1. The grid may be plated on one or both of its surfaces and supports a uniformly distributed lateral load. On two parallel edges, termed the "transverse edges," the beams are fixed. On the other two edges, termed the "longitudinal edges," the beams are freely supported. The beams in the longitudinal system are all identical and equally spaced, except the central longitudinal beam, which may be stiffer than the others in the system. The beams in the transverse system are all identical and equally spaced but their size and spacing are not necessarily the same as in the other direction.

The nomenclature is as follows:

- p = uniform lateral load
- E = modulus of elasticity
- μ = Poisson's ratio
- w = deflection
- I_x = moment of inertia of longitudinal stiffener (with effective width of plating)
- I_y = moment of inertia of transverse stiffener (with effective width of plating)
- I_m = moment of inertia of central longitudinal stiffener (with effective width of plating)
- i_x = equivalent unit moment of inertia of longitudinal stiffener $= \left(\frac{I_x}{s_x} + 2\,\frac{(I_m - I_x)}{b}\right)$
- i_y = unit moment of inertia of transverse stiffener $= \left(\frac{I_y}{s_y}\right)$
- i_f = average unit moment of inertia of flanges (plating) alone $= \left(\frac{i_{fx} + i_{fy}}{2}\right)$
- η = torsion coefficient $= \left(\frac{i_f}{\sqrt{i_x i_y}}\right)$
- σ_x = bending stress in flanges (plating) in the longitudinal direction
- τ_x = vertical shear stress in longitudinal stiffeners (webs)
- σ_y = bending stress in flanges (plating) in the transverse direction
- τ_y = vertical shear stress in transverse stiffeners (webs)
- A_x = sectional area of web of longitudinal stiffener
- A_m = sectional area of web of central longitudinal stiffener
- A_y = sectional area of web of transverse stiffener
- r_x = distance from neutral axis of longitudinal stiffener to most strained fiber
- r_y = distance from neutral axis of transverse stiffener to most strained fiber

This problem was solved in previous papers (1, 2)[2] approximately by means of the infinite-strip method, whereby the solution for a strip of such stiffened plating, infinitely long, freely supported on the edges, and with a single transverse support was obtained. The solution for the single transverse support was then simply superimposed upon the solution for another such

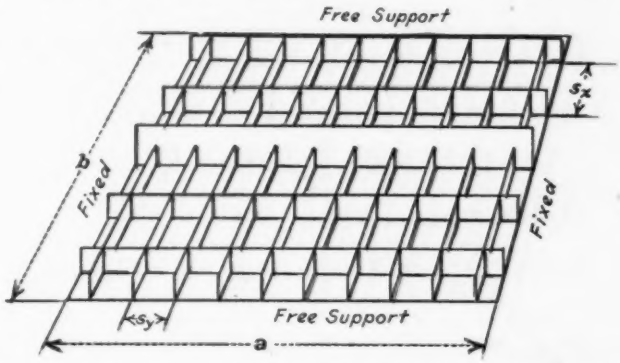

FIG. 1 A RECTANGULAR GRID OF ORTHOGONALLY INTERSECTING BEAMS

transverse support, which gave an approximation to the solution for the plate included between two such transverse supports. In the previous papers (1, 2), this method of solution was applied to the double-bottom structure of a ship. It is equally applicable to deck structure and many other elements of a ship, and also to many airplane structural problems. Under certain conditions, where the side ratio, that is, the ratio of the longitudinal dimension to the transverse dimension, is small, the approximate solution is inadequate; consequently, the following exact solution, applicable to all side ratios, has been developed. It follows, in general, the method used by Huber (3) for the orthotropic plate.

From Equation 30 in one of the author's previous papers (1), the deflection of the infinite strip, with no transverse support, under uniform lateral load, where $n = 1, 3, 5 \ldots$, is

$$w_p = \frac{4pb^4}{\pi^5 E i_y} \sum \frac{1}{n^5} \sin \frac{n\pi y}{b} \quad \ldots\ldots\ldots\ldots [1]$$

and the deflection due to the introduction of a negative transverse lineal load (of which rigid transverse support is a special case) is

---

[1] Lieutenant Commander, Construction Corps, U. S. Navy.

Presented at the National Meeting of the Applied Mechanics Division, Ann Arbor, Mich., June 20–21, 1940, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 10, 1941, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[2] Numbers in parentheses refer to the Bibliography at end of paper.

$$-w_b = \sum Ce^{-\alpha x}\left(\cos\beta x + \frac{\alpha}{\beta}\sin\beta x\right)\sin\frac{n\pi y}{b} = \sum CF(x)\sin\frac{n\pi y}{b} \quad [2]$$

where C is a constant depending on the lineal load, and the parameters α and β are

$$\left.\begin{aligned}\alpha &= \frac{n}{b}\frac{\pi}{\sqrt{2}}\sqrt[4]{\frac{i_y}{i_x}}\sqrt{(1+\eta)}\\ \beta &= \frac{\sqrt{(1-\eta)}}{\sqrt{(1+\eta)}}\alpha\end{aligned}\right\} \quad [3]$$

If it be imagined that there exists an infinite number of negative transverse lineal loads equally spaced across the infinite strip, then a panel between any two of these lineal loads will represent the rectangular element of stiffened plating under discussion, provided the boundary conditions at the locations of the lineal loads are suitably determined. If the spacing of these lineal loads is a then the deflection due to an infinite number of such loads may be written

$$-w_b = \sum_{m=0,1,2\ldots}\sum_n CF(ma + x)\sin\frac{n\pi y}{b} + \sum_{m=1,2,3\ldots}\sum_n CF(ma - x)\sin\frac{n\pi y}{b} \quad [4]$$

The first term represents the effect of all lineal loads to the left of a point whose x coordinate from any one station is x and the second term represents the effect of all such loads to the right of that point. The equation may also be written

$$-w_b = \sum_n CF'(x)\sin\frac{n\pi y}{b} \quad [5]$$

where the F' function is

$$F'(x) = \sum_{m=0,1,2} e^{-\alpha(ma+x)}\left[\cos\beta(ma+x) + \frac{\alpha}{\beta}\sin\beta(ma+x)\right] + \sum_{m=1,2,3} e^{-\alpha(ma-x)}\left[\cos\beta(ma-x) + \frac{\alpha}{\beta}\sin\beta(ma-x)\right] \quad [6]$$

The function $F'(x)$, after the trigonometric functions have been expanded and the terms collected, is

$$\begin{aligned}F'(x) = {} & e^{-\alpha x}\left(\cos\beta x + \frac{\alpha}{\beta}\sin\beta x\right)\sum_{m=0,1,2}(e^{-\alpha a})^m\cos\beta ma\\ & + e^{-\alpha x}\left(\frac{\alpha}{\beta}\cos\beta x - \sin\beta x\right)\sum_{m=0,1,2}(e^{-\alpha a})^m\sin\beta ma\\ & + e^{\alpha x}\left(\cos\beta x - \frac{\alpha}{\beta}\sin\beta x\right)\sum_{m=1,2,3,\ldots}(e^{-\alpha a})^m\cos\beta ma\\ & + e^{\alpha x}\left(\frac{\alpha}{\beta}\cos\beta x + \sin\beta x\right)\sum_{m=1,2,3\ldots}(e^{-\alpha a})^m\sin\beta ma \quad [7]\end{aligned}$$

The summations indicated in Equation [7] have finite values and, after evaluating them, rearranging, and eliminating the exponential functions in favor of hyperbolic functions, the equation becomes

$$F'(x) = \frac{1}{\cosh\alpha a - \cos\beta a}\left[\sinh\alpha(a-x)\cos\beta x + \frac{\alpha}{\beta}\cosh\alpha(a-x)\sin\beta x + \sinh\alpha x\cos\beta(a-x) + \frac{\alpha}{\beta}\cosh\alpha x\sin\beta(a-x)\right] \quad [8]$$

The boundary condition for determining the constant C in Equation [5] is that the deflection due to the uniform lateral load alone, according to Equation [1], must be equal and opposite to the deflection due to the infinite number of lineal loads, according to Equation [5], at the transverse supports, so that the two components of deflection cancel each other at the supports, where $x = a, 2a, 3a$, etc. Accordingly, for this condition to be satisfied

$$C = \frac{4pb^4}{\pi^5 Ei_y}\frac{1}{n^5}\frac{\cosh\alpha a - \cos\beta a}{\sinh\alpha a + \frac{\alpha}{\beta}\sin\beta a} \quad [9]$$

The total deflection between supports is, of course, the sum of that due to the uniform lateral load w_p and that due to the lineal loads w_b. These are given by Equations [1] and [5] with the value of C from Equation [9] inserted, so that the expression for total deflection is

$$w = \frac{4pb^4}{\pi^5 Ei_y}\sum\frac{1}{n^5}\sin\frac{n\pi y}{b}\left\{1 - \frac{1}{\sinh\alpha a + \frac{\alpha}{\beta}\sin\beta a}\times\left[\sinh\alpha(a-x)\cos\beta x + \frac{\alpha}{\beta}\cosh\alpha(a-x)\sin\beta a + \sinh\alpha x\cos\beta(a-x) + \frac{\alpha}{\beta}\cosh\alpha x\sin\beta(a-x)\right]\right\} \quad [10]$$

This is the fundamental equation for deflection of the orthogonally stiffened plate panel, clamped on two parallel edges and freely supported on the other two. Undoubtedly, the same result could be obtained by other means, i.e., by considering directly a panel of finite length, and imposing suitable boundary conditions on the two transverse boundaries. Such a solution would probably be more cumbersome to derive than that given here, particularly since the solution for the infinite strip is already available.

When dealing with rectangular panels of unstiffened plating, it is usual to frame the equations in terms of the ratio of the sides of the panel. A similar procedure can be adopted here, using instead of the actual side ratio a "virtual side ratio" ρ defined by

$$\rho = \frac{a}{b}\sqrt[4]{\frac{i_y}{i_x}} \quad [11]$$

Then in lieu of the parameters α and β, defined in Equation [3], it is more convenient to use dimensionless parameters, defined by

$$\left.\begin{aligned}\alpha' &= \frac{\alpha}{n}a = \frac{\pi}{\sqrt{2}}\rho\sqrt{(1+\eta)}\\ \beta' &= \frac{\beta}{n}a = \frac{\pi}{\sqrt{2}}\rho\sqrt{(1-\eta)}\end{aligned}\right\} \quad [12]$$

Then the deflection at the center of the panel, where $x = a/2$ and $y = b/2$, may be written

$$w_{a/2,\,b/2} = \frac{pb^4}{Ei_y}\left(\frac{5}{384} - \frac{8}{\pi^5}\sum\right) = K_1\frac{pb^4}{Ei_y} \quad [13]$$

where

$$\sum = \sum(-1)^{\frac{n-1}{2}}\frac{1}{n^5}\frac{\sinh n\frac{\alpha'}{2}\cos n\frac{\beta'}{2} + \frac{\alpha'}{\beta'}\cosh n\frac{\alpha'}{2}\sin n\frac{\beta'}{2}}{\sinh n\alpha' + \frac{\alpha'}{\beta'}\sin n\beta'}$$

For the special case that $\eta = 1$, and $i_x = i_y$, the summation becomes

$$\sum = \sum (-1)^{\frac{n-1}{2}} \frac{1}{n^5} \frac{\sinh n\frac{\pi}{2}\frac{a}{b} + n\frac{\pi}{2}\frac{a}{b}\cosh n\frac{\pi}{2}\frac{a}{b}}{\sinh n\pi\frac{a}{b} + n\pi\frac{a}{b}} \quad [14]$$

which is the form for the isotropic, unstiffened plate (4). The isotropy of the plate is indicated by the condition that $i_x = i_y$, and the fact that the structure is a solid plate, without stiffening, is indicated by the condition that the torsion coefficient η is equal to unity. This is clear from the physical meaning of η. It is, from its definition, $\eta = i_f/\sqrt{(i_x i_y)}$, the ratio of the unit stiffness of the material able to take horizontal shear stress to the geometric mean of the unit stiffnesses of the material able to take bending stresses in the two coordinate directions. In other words, η is a measure of the effect of horizontal shear or torsion. In a solid plate all material is equally able to take horizontal shear and bending stresses and $\eta = 1$. In a structure made up of horizontal plate and vertical stiffening webs, the webs are unable to take horizontal shear stresses (at least, to any significant degree) and here $0 < \eta < 1$. In a structure made up of a grid of intersecting webs, without horizontal plating, there is no material to take horizontal shear stresses and $\eta = 0$. The theory therefore comprehends unstiffened plates, stiffened plates (so long as the stiffening is orthotropic) and grids, and the equations can be used for any of these cases by choosing the proper value of η.

With the deflection function established, deriving the equations for bending stresses in the flanges (horizontal plating), and vertical shear stresses in the webs, is simply a matter of differentiating the function and applying Equations [1] and [2] from the author's previous paper (1) in the same manner as was done for the approximate solution. The maximum value of bending stress in the longitudinal direction occurs at the center of a transverse (fixed) boundary, with a secondary maximum at the center of the panel. The maximum value of bending stress in the transverse direction occurs at the center of the panel, since the longitudinal edges are freely supported. The maximums of shear in the vertical webs occur at the mid-points of the edges in each case.

The bending stress in the longitudinal direction at the center of a transverse boundary is

$$\sigma_{x(0,b/2)} = \frac{E}{1-\mu^2} r_x \frac{\partial^2 w}{\partial x^2}\Bigg]_{\substack{x=0\\y=b/2}}$$

$$= \frac{pb^2 r_x}{\sqrt{(i_x i_y)}}\left(\frac{1}{7.28} - \frac{8}{0.91\pi^3}\sum\right) = K_2 \frac{pb^2 r_x}{\sqrt{(i_x i_y)}} \quad [15]$$

with the value of 0.3 assigned to μ, and with

$$\sum = \sum (-1)^{\frac{n-1}{2}} \frac{1}{n^3} \frac{\frac{\alpha'}{\beta'}\sin n\beta'}{\sinh n\alpha' + \frac{\alpha'}{\beta'}\sin n\beta'}$$

The bending stress in the longitudinal direction at the center of the panel is

$$\sigma_{x(a/2,b/2)} = \frac{E}{1-\mu^2}\left(r_x\frac{\partial^2 w}{\partial x^2} + \mu r_y \frac{\partial^2 w}{\partial y^2}\right)\Bigg]_{\substack{x=a/2\\y=b/2}}$$

$$= \frac{pb^2 r_x}{\sqrt{(i_x i_y)}}\left[\frac{1}{1-\mu^2}\left(\frac{\mu'}{8} - \frac{8}{\pi^3}\sum\right)\right] = K_3 \frac{pb^2 r_x}{\sqrt{i_x i_y}} \quad [16]$$

where

$$\sum = \sum (-1)^{\frac{n-1}{2}} \frac{1}{n^3} \frac{(1+\mu')\sinh n\frac{\alpha'}{2}\cos n\frac{\beta'}{2} - (1-\mu')\frac{\alpha'}{\beta'}\cosh n\frac{\alpha'}{2}\sin n\frac{\beta'}{2}}{\sinh n\alpha' + \frac{\alpha'}{\beta'}\sin n\beta'}$$

and

$$\mu' = \mu\frac{r_y}{r_x}\sqrt{\frac{i_x}{i_y}}$$

To a close degree of approximation μ' may be assumed equal to μ, and with the value of 0.3 assigned to μ', the equation becomes

$$\sigma_{x(a/2,b/2)} = \frac{pb^2 r_x}{\sqrt{(i_x i_y)}}\left(\frac{0.3}{7.28} - \frac{8}{0.91\pi^3}\sum\right) = K_3\frac{pb^2 r_x}{\sqrt{(i_x i_y)}} \quad [17]$$

where

$$\sum = \sum (-1)^{\frac{n-1}{2}} \frac{1}{n^3} \frac{1.3\sinh n\frac{\alpha'}{2}\cos n\frac{\beta'}{2} - 0.7\frac{\alpha'}{\beta'}\cosh n\frac{\alpha'}{2}\sin n\frac{\beta'}{2}}{\sinh n\alpha' + \frac{\alpha'}{\beta'}\sin n\beta'}$$

The bending stress in the transverse direction at the center of the panel is

$$\sigma_{y(a/2,b/2)} = \frac{E}{1-\mu^2}\left(r_y\frac{\partial^2 w}{\partial y^2} + \mu r_x\frac{\partial^2 w}{\partial x^2}\right)\Bigg]_{\substack{x=a/2\\y=b/2}}$$

$$= \frac{pb^2 r_y}{i_y}\left(\frac{1}{7.28} - \frac{8}{0.91\pi^3}\sum\right) = K_4\frac{pb^2 r_y}{i_y} \quad [18]$$

where

$$\sum = \sum (-1)^{\frac{n-1}{2}} \frac{1}{n^3} \frac{1.3\sinh n\frac{\alpha'}{2}\cos n\frac{\beta'}{2} + 0.7\frac{\alpha'}{\beta'}\cosh n\frac{\alpha'}{2}\sin n\frac{\beta'}{2}}{\sinh n\alpha' + \frac{\alpha'}{\beta'}\sin n\beta'}$$

with the value of 0.3 assigned to μ, and using again the close approximation that

$$\frac{r_x}{r_y}\sqrt{\frac{i_y}{i_x}} = 1 \quad [19]$$

The shear stress in the longitudinal webs at a transverse boundary is

$$\tau_{x(0,y)} = -E\frac{i_x s_x}{A_x}\frac{\partial^2 w}{\partial x^2}\Bigg]_{x=0} = \frac{pbi_x s_x}{A_x\sqrt[4]{(i_x^3 i_y)}}$$

$$\left[\frac{4\sqrt{2}}{\pi^2}\sqrt{(1+\eta)}\sum\frac{1}{n^2}\frac{\cosh n\alpha' - \cos n\beta'}{\sinh n\alpha' + \frac{\alpha'}{\beta'}\sin n\beta'}\sin\frac{n\pi y}{b}\right] \quad [20]$$

At the center of a transverse boundary this becomes

$$\tau_{x(0,\,b/2)} = \frac{pbI_m}{A_m\sqrt[4]{(i_x{}^2 i_y)}}\left[\frac{4\sqrt{2}}{\pi^2}\sqrt{(1+\eta)}\sum\right] = K_5\frac{pbI_m}{A_m\sqrt[4]{(i_x{}^2 i_y)}} \quad \ldots [21]$$

where

$$\sum = \sum (-1)^{\frac{n-1}{2}}\frac{1}{n^2}\frac{\cosh n\alpha' - \cos n\beta'}{\sinh n\alpha' + \frac{\alpha'}{\beta'}\sin n\beta'}$$

and this is the maximum value unless the cross-sectional area of the central longitudinal stiffener A_m is considerably greater than the area of the other longitudinal stiffeners A_s, in which case the maximum value of vertical shear stress will occur in the first web adjacent to the central longitudinal web. Equation [20] would then be used for the maximum. In case the central longitudinal web is identical with the other longitudinal webs, Equation [21] becomes

$$\tau_{x(0,\,b/2)} = K_5\frac{pbs_x}{A_x}\sqrt[4]{\frac{i_x}{i_y}} \quad \ldots [22]$$

The vertical shear stress in the transverse web at the center of a longitudinal boundary is

$$\tau_{y(a/2,\,0)} = -\frac{Es_y}{A_y}\left(i_y\frac{\partial^3 w}{\partial y^3} + i_f\frac{\partial^3 w}{\partial x^2\partial y}\right)\Bigg]_{\substack{x=a/2\\ y=0}}$$

$$= \frac{pbs_y}{A_y}\left[\frac{1}{2} - \frac{8}{\pi^2}\sum\right] = K_6\frac{pbs_y}{A_y} \quad \ldots [23]$$

where

$$\sum = \sum\frac{1}{n^2}\,\frac{(1+\eta)\sinh n\frac{\alpha'}{2}\cos n\frac{\beta'}{2} + (1-\eta)\frac{\alpha'}{\beta'}\cosh n\frac{\alpha'}{2}\sin n\frac{\beta'}{2}}{\sinh n\alpha' + \frac{\alpha'}{\beta'}\sin n\beta'}$$

It will be noted from Equations [13], [15], [17], [18], [21], and [23] that the maximum deflection, bending, and shear stresses are all expressed in terms of the loading, the dimensions of the structure, and the modulus of elasticity, multiplied by coefficients (the K's) which are functions only of the virtual side ratio ρ and the torsion coefficient η. Thus it is possible to represent the numerical values of these coefficients (K's) by contour curves for various values of η with the values of the virtual side ratio as abscissa. Such curves for the maximum bending stress in the longitudinal direction, calculated from Equation [15], are shown in Fig. 2.

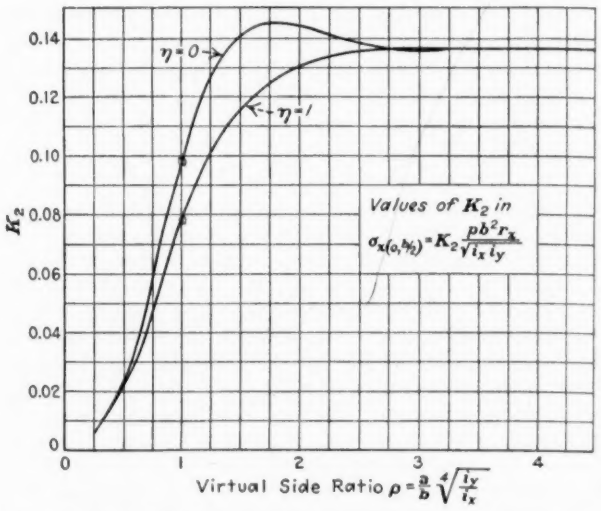

FIG. 2 CURVES FOR MAXIMUM BENDING STRESS IN THE LONGITUDINAL DIRECTION CALCULATED FROM EQUATION [15]

Since for the unstiffened plate η is equal to unity, the curve for that value of η will be identical with the curve for the unstiffened plate with the same loading and boundary conditions, as given, for example, in the curves for case 5 in the Wojtaszak Design Data (5). Also, if the stiffening on a stiffened plate is such that η may be assumed equal to unity as an approximation, then curves for unstiffened plating may be used for stiffened plating, provided the "virtual side ratio" is taken into account. Curves for other values of η can be used for design purposes for stiffened plating exactly as the Wojtaszak curves (5) are used for unstiffened plating. The calculation of maximum deflection and stresses in orthogonally stiffened plating, with the assumed loading and boundary conditions, becomes no more difficult than the calculation of equivalent values in unstiffened plating.

Some Observations on the Theory of Contact Pressures

By STEWART WAY,[1] EAST PITTSBURGH, PA.

The stress system in a semi-infinite elastic solid with given normal surface loading is of importance in many problems of machine and structural design and strength of materials. It often happens in such cases that the stresses in which one is primarily interested are those in the surface of the body. This paper presents some observations that can be made regarding the stresses and displacements in the surface.

SOME of the observations that can be made regarding stresses and displacements in a semi-infinite elastic solid with given normal surface loading are briefly as follows:

(*a*) There are a number of cases in which an infinite number of different load distributions inside a region R of the surface produce the same system of stresses and horizontal displacements in the surface outside R.

(*b*) The horizontal displacements in the surface are shown to stand in a simple proportionality relation to the slopes in the x and y directions of a stretched membrane loaded in the same way as the elastic solid. The stresses in the surface are related to the second derivatives of the membrane deflection.

(*c*) An analogy can be set up between the stresses in the surface of the semi-infinite solid, when it carries a loading $q = f(x)$ along a line segment from $x = -c$, $y = 0$ to $x = c$, $y = 0$, and the shearing stresses on certain planes in a semi-infinite solid in a plane state of strain loaded by the pressure distribution $p = f(x)$ along the band between $x = -c$ and $x = +c$. The same analogy also holds when the latter body is a thin sheet in a state of plane stress.

The Semi-Infinite Body With Vertical Loading on the Surface

The first serious attempt to deal with this problem was made by Lamé and Clapeyron in 1828(1).[2] However, they used a series method which led to quadruple integral expressions and was hence of slight practical value. It was not until 1878 that Boussinesq (2), using the method of singularities developed earlier by Green in his potential theory, obtained a satisfactory solution.

Let the plane $z = 0$ be the bounding surface and let the body fill all space for $z > 0$. Suppose a concentrated load P is applied at the point $(x', y', 0)$ as shown in Fig. 1. We want to know the displacements and stresses at a general point (x, y, z). Let

$$\psi = P/\rho \quad [1]$$

$$\phi = P \log (\rho + z) \quad [2]$$

$$\rho = \sqrt{[(x-x')^2 + (y-y')^2 + z^2]} \quad [3]$$

Boussinesq showed that the displacements and stresses at the point x, y, z could be expressed in terms of ψ and ϕ as follows

$$\left.\begin{aligned} u &= -\frac{z}{4\pi G}\frac{\partial\psi}{\partial x} - \frac{1-2\mu}{4\pi G}\frac{\partial\phi}{\partial x} \\ v &= -\frac{z}{4\pi G}\frac{\partial\psi}{\partial y} - \frac{1-2\mu}{4\pi G}\frac{\partial\phi}{\partial y} \\ w &= -\frac{z}{4\pi G}\frac{\partial\psi}{\partial z} + \frac{1-\mu}{2\pi G}\psi \end{aligned}\right\} \quad [4]$$

$$\left.\begin{aligned} \sigma_x &= \frac{\mu}{\pi}\frac{\partial\psi}{\partial z} - \frac{z}{2\pi}\frac{\partial^2\psi}{\partial x^2} - \frac{1-2\mu}{2\pi}\frac{\partial^2\phi}{\partial x^2} & \tau_{xy} &= -\frac{z}{2\pi}\frac{\partial^2\psi}{\partial x\partial y} - \frac{1-2\mu}{2\pi}\frac{\partial^2\phi}{\partial x\partial y} \\ \sigma_y &= \frac{\mu}{\pi}\frac{\partial\psi}{\partial z} - \frac{z}{2\pi}\frac{\partial^2\psi}{\partial y^2} - \frac{1-2\mu}{2\pi}\frac{\partial^2\phi}{\partial y^2} & \tau_{yz} &= -\frac{z}{2\pi}\frac{\partial^2\psi}{\partial y\partial z} \\ \sigma_z &= \frac{1}{2\pi}\frac{\partial\psi}{\partial z} - \frac{z}{2\pi}\frac{\partial^2\psi}{\partial z^2} & \tau_{zx} &= -\frac{z}{2\pi}\frac{\partial^2\psi}{\partial z\partial x} \end{aligned}\right\} \quad [5]$$

For any normal surface loading over a region R, Equations [4] and [5] remain valid if we simply form the integrals, as did Boussinesq, of the right-hand members of Equations [1] and [2], replacing P by $p\,dx'dy'$. For any distributed load over R, therefore, ψ and ϕ become

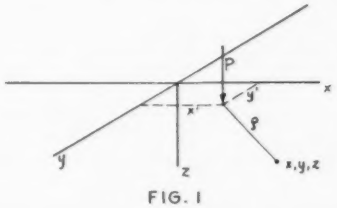

FIG. 1

$$\psi = \int_R\int \frac{p}{\rho}\,dx'dy' \quad [6]$$

$$\phi = \int_R\int p \log (\rho + z)\,dx'dy' \quad [7]$$

Equations [1] and [2] may now be regarded merely as special cases of Equations [6] and [7]. Coordinates with primes will always refer to a point where a load is acting.

One may easily verify by differentiation that ψ and ϕ satisfy Laplace's equation everywhere inside the body

$$\frac{\partial^2\psi}{\partial x^2} + \frac{\partial^2\psi}{\partial y^2} + \frac{\partial^2\psi}{\partial z^2} = 0; \quad \frac{\partial^2\phi}{\partial x^2} + \frac{\partial^2\phi}{\partial y^2} + \frac{\partial^2\phi}{\partial z^2} = 0 \quad [8]$$

It should be noted, however, that ψ does not satisfy Laplace's equation in the loaded area itself, for $\partial\psi/\partial z$ is discontinuous at $z = 0$ for points inside R, as shown in the following:

In case the load is distributed along a curve C with intensity ω per unit length, the integrals for ψ and ϕ become

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 10, 1941, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

$$\psi = \int_C \frac{\omega}{\rho}\, ds \quad [9]$$

$$\phi = \int_C \omega \log (\rho + z) ds \quad [10]$$

where ds is an element of arc of C.

We also observe that in all cases

$$\psi = \partial\phi/\partial z \quad [11]$$

We see that ψ, as defined by Equation [6], is the Newtonian potential due to a distribution of matter of surface density p in the plane $z = 0$. Suppose we have a volume V whose surface is S

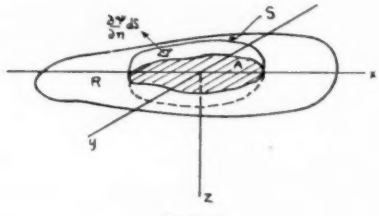

FIG. 2

and which intersects the plane $z = 0$ in an area A, as shown in Fig. 2. The theorem of Gauss then takes the form

$$\int_S \int \frac{\partial\psi}{\partial n}\, dS = -4\pi \int_A \int p dA \quad [12]$$

If we take for the volume V a short right cylinder whose ends are in the planes $z = \delta z$, $z = -\delta z$ and whose section is dS, we will have $dS = dA$, and by letting δz approach zero we will obtain

$$\left(\frac{\partial\psi}{\partial z}\right)_+ - \left(\frac{\partial\psi}{\partial z}\right)_- = -4\pi p \quad [13]$$

There is thus a discontinuity in $\partial\psi/\partial z$ in the plane $z = 0$ for points inside R of amount $-4\pi p$. Outside R, since $p = 0$, there is no discontinuity in $\partial\psi/\partial z$. Since ψ is symmetrical about the plane $z = 0$, we have

$$\left(\frac{\partial\psi}{\partial z}\right)_+ = -2\pi p \quad [14]$$

Hence, for $z = 0$, the equation for σ_z in Equations [5] gives $\sigma_z = -p$ inside R and $\sigma_z = 0$ outside R, since p is then equal to zero.

For the displacements and stresses in the surface $z = 0$ we will introduce the subscript zero. From Equations [4] and [5] these quantities become

$$u_0 = -\frac{1-2\mu}{4\pi G}\frac{\partial\phi_0}{\partial x};\quad v_0 = -\frac{1-2\mu}{4\pi G}\frac{\partial\phi_0}{\partial y};\quad w_0 = \frac{1-\mu}{2\pi G}\psi_0 \quad [15]$$

$$\left.\begin{aligned} &\sigma_{x0} = -2\mu p - \frac{1-2\mu}{2\pi}\frac{\partial^2\phi_0}{\partial x^2};\quad \tau_{xy0} = -\frac{1-2\mu}{2\pi}\frac{\partial^2\phi_0}{\partial x\partial y}\\ &\sigma_{y0} = -2\mu p - \frac{1-2\mu}{2\pi}\frac{\partial^2\phi_0}{\partial y^2};\quad \tau_{yz0} = 0\\ &\sigma_{z0} = -p;\qquad\qquad \tau_{zx0} = 0 \end{aligned}\right\} \quad [16]$$

in which ψ_0 and ϕ_0 are defined by the integrals

$$\psi_0 = \int_R \int \frac{p}{\rho_0}\, dx'dy' \quad [17]$$

$$\phi_0 = \int_R \int p \log \rho_0 dx'dy' \quad [18]$$

where

$$\rho_0 = \sqrt{[(x-x')^2 + (y-y')^2]} \quad [19]$$

If we use the symbol Δ for the Laplacian operator in two dimensions

$$\Delta = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \quad [20]$$

the function ϕ_0 will satisfy Poisson's equation in its two-dimensional form

$$\Delta\phi_0 = 2\pi p \quad [21]$$

Everywhere outside R where $p = 0$, we will have

$$\Delta\phi_0 = 0 \quad [22]$$

The sum of the stresses σ_{x0} and σ_{y0} becomes

$$\sigma_{x0} + \sigma_{y0} = -(1 + 2\mu)p \quad [23]$$

which reduces to zero everywhere outside R.

If A is a region in the plane $z = 0$ which contains part or all of R,

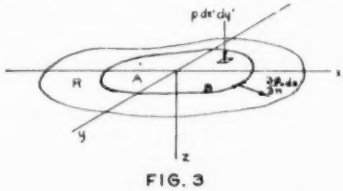

FIG. 3

and if B is the boundary of A, as shown in Fig. 3, Gauss's theorem in two dimensions tells us that

$$\oint_B \left(\frac{\partial\phi_0}{\partial n}\right) ds = 2\pi \int_A \int p dx'dy' \quad [24]$$

or the total outward flux of the gradient of a logarithmic potential ϕ_0 due to sources p per unit area in a region A is equal to 2π times the total of the sources in A.

If the loading is of intensity ω along a curve C, we may apply Gauss's theorem, Equation [24], to a small rectangle enclosing an element ds of C and derive the value of the discontinuity in $\partial\phi_0/\partial n$ at C, or

$$\left(\frac{\partial\phi_0}{\partial n}\right)_1 - \left(\frac{\partial\phi_0}{\partial n}\right)_2 = 2\pi\omega \quad [25]$$

We may call attention to the fact that the theory of elasticity breaks down near curves carrying loading along their length and near concentrated loads, as the displacements become discontinuous or excessively large at such places.

In terms of polar coordinates, the displacements and stresses in the surface are given by

$$\delta_{r0} = -\frac{1-2\mu}{4\pi G}\frac{\partial\phi_0}{\partial r};\quad \delta_{\theta 0} = -\frac{1-2\mu}{4\pi G}\frac{1}{r}\frac{\partial\phi_0}{\partial\theta};\quad w_0 = \frac{1-\mu}{2\pi G}\psi_0 \quad [26]$$

$$\left.\begin{aligned} &\sigma_{r0} = -2\mu p - \frac{1-2\mu}{2\pi}\frac{\partial^2\phi_0}{\partial r^2};\qquad \sigma_{z0} = -p\\ &\sigma_{\theta 0} = -2\mu p - \frac{1-2\mu}{2\pi}\left(\frac{1}{r}\frac{\partial\phi_0}{\partial r} + \frac{1}{r^2}\frac{\partial^2\phi_0}{\partial\theta^2}\right);\\ &\tau_{r\theta 0} = -\frac{1-2\mu}{2\pi}\frac{\partial}{\partial r}\left(\frac{1}{r}\frac{\partial\phi_0}{\partial\theta}\right) \end{aligned}\right\} \quad [27]$$

Different Loadings Producing the Same Surface Stresses

There are a number of cases in which the logarithmic potential ϕ_0 defined by Equation [18] will be of a certain form outside a

region R for an infinite number of different load distributions inside R. It follows that in such cases, an infinite number of different load distributions inside R will give rise to the same stresses and horizontal displacements in the surface outside R. We here list some of these cases. Each one is discussed more fully in the Appendix.

Case I. Let R be a circle of radius a with center at the origin. Any radially symmetrical pressure distribution $p = f(r')$ within R as shown in Fig. 4*a* will produce the same logarithmic potential ϕ_0

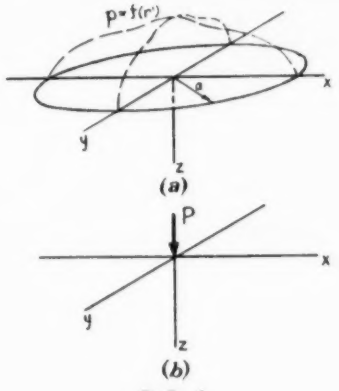

FIG. 4

and the same horizontal displacements and stresses in the surface outside R as a concentrated force P at the origin as shown in Fig. 4*b*, providing

$$P = \int_0^a 2\pi r' f(r') dr' \quad \ldots\ldots\ldots\ldots\ldots [28]$$

that is, if P is the total of the pressures p.

For both cases of loading, if $r > a$, we will have

$$\phi_0 = P \log r; \quad \delta_{r0} = -\frac{1-2\mu}{4\pi G}\cdot\frac{P}{r}; \quad \delta_{\theta 0} = 0 \ldots\ldots [29]$$

$$\left.\begin{aligned} \sigma_{r0} &= \frac{1-2\mu}{2\pi}\cdot\frac{P}{r^2}; \quad \sigma_{z0} = 0 \\ \sigma_{\theta 0} &= -\frac{1-2\mu}{2\pi}\cdot\frac{P}{r^2}; \quad \tau_{r\theta 0} = 0 \end{aligned}\right\} \ldots\ldots\ldots [30]$$

Any self-equilibrating vertical loading, radially symmetrical, distributed over R will produce no stresses or horizontal displacements in the surface outside R.

Case II. Suppose we have a loading ω per unit length of arc around a circle of radius a which varies according to the law

$$\omega = \frac{m}{\pi a^2}\cos\theta' \ldots\ldots\ldots\ldots\ldots [31]$$

as shown in Fig. 5*a*. This loading will produce the same logarithmic potential and the same stresses and horizontal displacements in the surface outside the circle as a concentrated couple m at the origin, with axis along OY, as shown in Fig. 5*b*. The logarithmic potential and the horizontal displacements and stresses will be, for $r > a$

$$\phi_0 = -\frac{m}{r}\cos\theta; \quad \delta_{r0} = -\frac{1-2\mu}{4\pi G}\cdot\frac{m}{r^2}\cos\theta;$$

$$\delta_{\theta 0} = -\frac{1-2\mu}{4\pi G}\cdot\frac{m}{r^2}\sin\theta \ldots\ldots [32]$$

$$\left.\begin{aligned} \sigma_{r0} &= \frac{1-2\mu}{\pi}\cdot\frac{m}{r^3}\cos\theta; \quad \sigma_{z0} = 0 \\ \sigma_{\theta 0} &= -\frac{1-2\mu}{\pi}\cdot\frac{m}{r^3}\cos\theta; \quad \tau_{r\theta 0} = \frac{1-2\mu}{\pi}\cdot\frac{m}{r^3}\sin\theta \end{aligned}\right\} \ldots [33]$$

These expressions are, of course, also valid for $r < a$ for the concentrated moment loading.

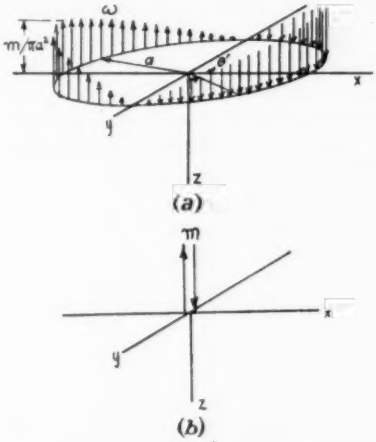

FIG. 5

The moment of the ω loading about OY is equal to m.

Cases of loading of the form

$$p = f(r')\cos\theta' \ldots\ldots\ldots\ldots\ldots [34]$$

over a circle of radius a can be investigated by superposition of ring loadings of the type shown in Fig. 5*a*. The equivalent couple M at the origin with axis along OY would be the moment of the p loading about OY.

Case III. Let $p(x', y')$ be any load distribution over a region R' and let C be a closed curve outside of and enclosing R', as shown in Fig. 6*a*. Let R be the region bounded by the curve C

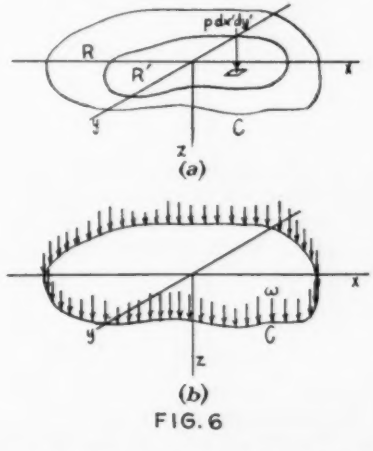

FIG. 6

and let ϕ_0 be the logarithmic potential due to loading p. The logarithmic potential, the stresses, and horizontal displacements outside R due to loading $p(x', y')$ will be the same as those due to a loading ω distributed along C as shown in Fig. 6*b* where ω is defined by the relation

$$\omega = \frac{1}{2\pi}\left(\frac{\partial\phi'}{\partial n_1} - \frac{\partial\phi'}{\partial n_2}\right) \ldots\ldots\ldots\ldots [35]$$

Here, ϕ' is a logarithmic potential function defined by the requirements that $\Delta\phi' = 0$ inside C and $\phi' = \phi_0$ outside C; the outward normal component of the gradient of ϕ' takes the value $\partial\phi'/\partial n_1$ just outside C and the value $\partial\phi'/\partial n_2$ just inside C. The potential ϕ' is that due to the loading ω alone. The total of the ω loading is equal to the total amount of the p loading on R'.

An important subcase of III is that for which ϕ_0 is constant on C. Then ϕ' is constant in R and ω is simply given by

$$\omega = \frac{1}{2\pi}\left(\frac{\partial\phi_0}{\partial n}\right)_C \quad \ldots\ldots [36]$$

An interesting example of this subcase is the following. Let the loaded region be a line segment extending from $x = -c$, $y = 0$ to $x = c$, $y = 0$, and let the intensity of loading per unit length of this segment be given by

$$q = \frac{Q}{\pi c\sqrt{\left[1 - \left(\frac{x'^2}{c^2}\right)\right]}} \quad \ldots\ldots [37]$$

where Q is the total amount of the load. This loading is represented in Fig. 7*a*. The logarithmic potential ϕ_0 due to this loading, the horizontal displacements, and the stresses in the surface will be the same as those due to a loading ω distributed around an ellipse C, whose foci are the end points of the line segment, where ω varies according to the law

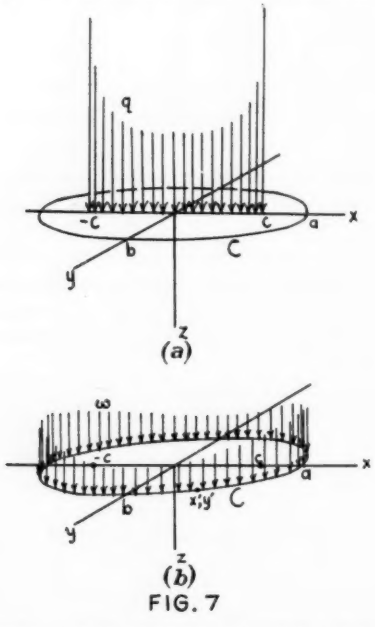

FIG. 7

$$\omega = \frac{Q}{2\pi ab\sqrt{\left(\frac{x'^2}{a^4} + \frac{y'^2}{b^4}\right)}} \quad \ldots\ldots [38]$$

Here a and b are the semiaxes of the ellipse, and (x', y') is a point on the ellipse. The total of the ω loading is Q. This loading is shown in Fig. 7*b*.

We may go one step further and replace the ellipse C by a narrow ring between the geometrically similar ellipses

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \quad \ldots\ldots [39]$$

$$\frac{x^2}{(a - ak)^2} + \frac{y^2}{(b - bk)^2} = 1 \quad \ldots\ldots [40]$$

and apply on this ring the uniform pressure

$$p_0 = \frac{Q}{2\pi abk} \quad \ldots\ldots [41]$$

The load per unit length on the ring will be everywhere equal to ω, and the total load is Q. The outer boundary of the ring, given by Equation [39], is the ellipse C. If the ring is very narrow the logarithmic potential due to the loading upon it, the horizontal diplacements, and stresses outside C will be the same as for the ω loading on C or the q loading on the line segment.

To describe this stress system it is convenient to use elliptic coordinates λ, ν defined by

$$\left.\begin{aligned} \frac{x^2}{c^2\cosh^2\lambda} + \frac{y^2}{c^2\sinh^2\lambda} &= 1 \\ \frac{x^2}{c^2\cos^2\nu} - \frac{y^2}{c^2\sin^2\nu} &= 1 \end{aligned}\right\} \quad \ldots\ldots [42]$$

Outside C, the logarithmic potential, the horizontal displacements, and stresses will be

$$\phi_0 = Q\left(\lambda - \log\frac{2}{c}\right);\ \delta_\lambda = -\frac{1-2\mu}{4\pi G}Qh;\ \delta_\nu = 0 \quad \ldots [43]$$

$$\left.\begin{aligned} \sigma_\lambda &= \frac{1-2\mu}{2\pi}Qc^2h^4\sinh\lambda\cosh\lambda \\ \sigma_\nu &= -\frac{1-2\mu}{2\pi}Qc^2h^4\sinh\lambda\cosh\lambda \\ \tau_{\lambda\nu} &= \frac{1-2\mu}{2\pi}Qc^2h^4\sin\nu\cos\nu \end{aligned}\right\} \quad \ldots\ldots [44]$$

in which

$$h = \frac{1}{c\sqrt{(\cos^2\nu\sinh^2\lambda + \sin^2\nu\cosh^2\lambda)}} \quad \ldots\ldots [45]$$

The value of λ on the ellipse C is $\lambda_0 = \cosh^{-1} a/c$. The quantity h is the magnitude of the gradient of λ or the gradient of ν. Inside C, for the case of the loaded ellipse, the stresses and horizontal displacements are zero, since ϕ_0 is constant in that region.

Case IV. Any two uniformly loaded confocal elliptical areas give rise to the same potential ϕ_0 in the region external to both if the total loads are the same. Consequently, the stresses and horizontal displacements due to two such loadings are alike in the region external to both.

More specifically, let C and C_1 be ellipses whose equations are

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \quad \ldots\ldots [46]$$

$$\frac{x^2}{a_1^2} + \frac{y^2}{b_1^2} = 1 \quad \ldots\ldots [47]$$

and let

$$a^2 - b^2 = a_1^2 - b_1^2 = c^2 \quad \ldots\ldots [48]$$

so that the ellipses are confocal. We assume $a > a_1$, $b > b_1$. Let p_0 be the pressure on the area within C and p_1 be the pressure on the area within C_1. (It is not meant that we are superimposing these loadings; we are comparing them, assuming each exists separately.) The total loads on the two ellipses will be alike if

$$p_1a_1b_1 = p_0ab = Q/\pi \quad \ldots\ldots [49]$$

Both loaded areas will then give rise to the same logarithmic potential outside C.

Now, let b_1 approach zero while a_1 approaches c and $p_1a_1b_1$ re-

mains constant. The inner ellipse C_1 approaches the line segment from $(-c, 0)$ to $(+c, 0)$ and the loading becomes a force per unit length on this segment of amount

$$q = \frac{2Q}{\pi c}\sqrt{\left[1 - \left(\frac{x'^2}{c^2}\right)\right]} \quad \ldots\ldots [50]$$

The stresses and horizontal displacements in the surface outside C due to the q loading, as shown in Fig. 8*a*, will be the same as

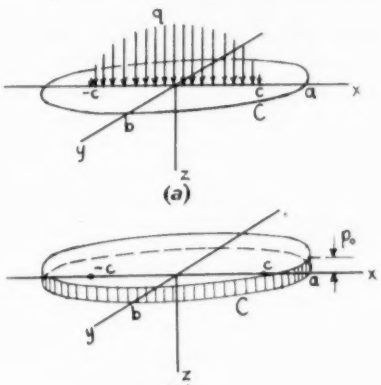

FIG. 8

those due to the uniformly loaded ellipse shown in Fig. 8*b*. These quantities, for the region outside C in both cases, will be

$$\left.\begin{aligned} u_0 &= -\frac{1-2\mu}{2\pi G}\left(\frac{Qx}{\sqrt{c^2+\gamma}\,(\sqrt{c^2+\gamma}+\sqrt{\gamma})}\right); \\ v_0 &= -\frac{1-2\mu}{2\pi G}\left(\frac{Qy}{\sqrt{\gamma}\,(\sqrt{c^2+\gamma}+\sqrt{\gamma})}\right) \end{aligned}\right\} \quad \ldots [51]$$

$$\left.\begin{aligned} \sigma_{x0} &= \frac{(1-2\mu)Q}{\pi c^2}\left[\sqrt{\frac{\gamma+c^2}{\gamma}}\left(\frac{\gamma^2}{\gamma^2+y^2c^2}\right)-1\right] \\ \sigma_{y0} &= -\sigma_{x0} \\ \tau_{xy0} &= \frac{(1-2\mu)}{\pi}\cdot\frac{Qxy\sqrt{\gamma}}{\sqrt{c^2+\gamma}\,(\gamma^2+y^2c^2)} \end{aligned}\right\} \quad \ldots [52]$$

where

$$\gamma = \frac{1}{2}\left\{x^2+y^2-c^2+\sqrt{[(x^2+y^2-c^2)^2+4y^2c^2]}\right\} \quad \ldots [53]$$

These expressions are also valid inside C for the case of the loaded line segment shown in Fig. 8*a*.

Case V. Compare the effects of a semiellipsoidal loading which varies according to the relation

$$p = p_0\sqrt{\left(1-\frac{x'^2}{a^2}-\frac{y'^2}{b^2}\right)} \quad \ldots\ldots [54]$$

over an ellipse C of semiaxes a and b, with a parabolic loading along a line segment from $(-c, 0)$ to $(+c, 0)$ which is given by

$$q = \frac{\pi abp_0}{2c}\left(1-\frac{x'^2}{c^2}\right) \quad \ldots\ldots [55]$$

where

$$c = \sqrt{(a^2-b^2)}$$

The two loadings are shown in Figs. 9*a* and 9*b*. The total amounts of the two loadings are alike, being

$$Q = \frac{2}{3}\pi abp_0 \quad \ldots\ldots [56]$$

The horizontal displacements and stresses outside C will be the same for both cases of loading. They are found to be

$$\left.\begin{aligned} u_0 &= -\frac{(1-2\mu)p_0ab}{8Gc}\left[\frac{2xy}{c^2}\left(\tan^{-1}\frac{x-c}{y}-\tan^{-1}\frac{x+c}{y}\right)\right. \\ &\left.+\frac{1}{2}\left(\frac{x^2}{c^2}-\frac{y^2}{c^2}-1\right)\log\frac{(x-c)^2+y^2}{(x+c)^2+y^2}+\frac{2x}{c}\right] \\ v_0 &= -\frac{(1-2\mu)p_0ab}{8Gc}\left[\left(\frac{x^2}{c^2}-\frac{y^2}{c^2}-1\right)\left(\tan^{-1}\frac{x-c}{y}\right.\right. \\ &\left.\left.-\tan^{-1}\frac{x+c}{y}\right)-\frac{2y}{c}-\frac{xy}{c^2}\log\frac{(x-c)^2+y^2}{(x+c)^2+y^2}\right] \end{aligned}\right\} \quad [57]$$

$$\left.\begin{aligned} \sigma_{x0} &= -\frac{(1-2\mu)}{2c^2}p_0ab\left[2+\frac{x}{2c}\log\frac{(x-c)^2+y^2}{(x+c)^2+y^2}\right. \\ &\left.+\frac{y}{}\left(\tan^{-1}\frac{x-c}{y}-\tan^{-1}\frac{x+c}{y}\right)\right] \\ \sigma_{y0} &= -\sigma_{x0} \\ \tau_{xy0} &= -\frac{(1-2\mu)}{2c^2}p_0ab\left[\frac{x}{c}\left(\tan^{-1}\frac{x-c}{y}\right.\right. \\ &\left.\left.-\tan^{-1}\frac{x+c}{y}\right)-\frac{y}{2c}\log\frac{(x-c)^2+y^2}{(x+c)^2+y^2}\right] \end{aligned}\right\} \quad [58]$$

These expressions are also valid inside C for the case of the q loading.

At the ends of the major and minor axes the stresses in the surface become

$$\left.\begin{aligned} (\sigma_{x0})_a &= -(\sigma_{y0})_a = -\frac{(1-2\mu)}{2c^2}p_0ab\left(2+\frac{a}{c}\log\frac{a-c}{a+c}\right) \\ (\sigma_{x0})_b &= -(\sigma_{y0})_b = -\frac{(1-2\mu)}{2c^2}p_0ab\left(2-\frac{2b}{c}\tan^{-1}\frac{c}{b}\right) \\ (\tau_{xy0})_a &= (\tau_{xy0})_b = 0 \end{aligned}\right\} \quad [59]$$

These values agree with those obtained by Belajef, referred to by Timoshenko (3).

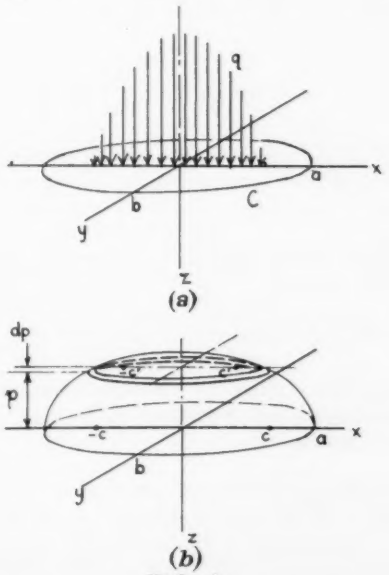

FIG. 9

The loading of Fig. 9*b* is that which results when two elastic solids with slightly curved surfaces are brought into contact (4, 5, 6).

Case VI. Compare the effects of a uniform loading of intensity $Q/2c$ per unit length along a line segment from $(-c, 0)$ to $(+c, 0)$, as shown in Fig. 10*a*, with those of the loading due to a perfectly

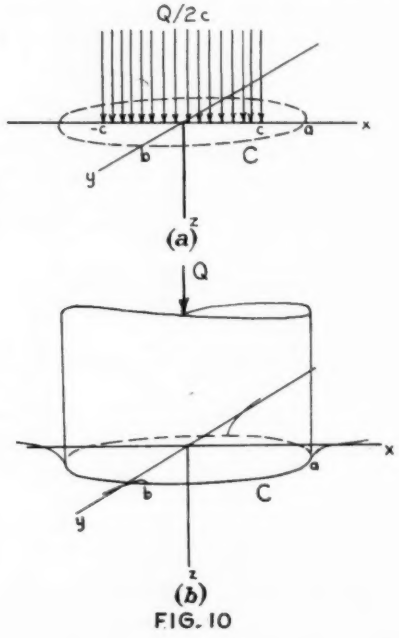

FIG. 10

rigid punch in the form of an elliptical cylinder with a flat end pressed against the surface with a force Q, as shown in Fig. 10*b*. Call the periphery of the loaded area C. The elliptical section of the punch and its position on the surface are assumed to be such that $(-c, 0)$ and $(+c, 0)$ are the foci of the ellipse C.

J. Boussinesq (7) called attention to the fact that the problem of calculating the pressure distribution under any rigid flat-ended punch is essentially the same as that of calculating the electric-charge distribution in a thin conducting disk of the same shape as the cross section of the punch, and concluded that the pressure distribution beneath the elliptical punch is given by

$$p = \frac{Q}{2\pi ab\sqrt{\left(1 - \frac{x'^2}{a^2} - \frac{y'^2}{b^2}\right)}} \quad \ldots\ldots [60]$$

The potential ϕ_0 due to either the p loading under the punch or the loading $Q/2c$ along the segment, for the region outside C will be

$$\phi_0 = -\frac{Q}{4c}\left[(x-c)\log\{(x-c)^2 + y^2\} - (x+c)\log\{(x+c)^2 + y^2\} + 4c + 2y\left(\tan^{-1}\frac{x-c}{y} - \tan^{-1}\frac{x+c}{y}\right)\right] \quad [61]$$

which is also valid within C for the loaded segment. The horizontal displacements and the stresses in the surface, outside C, for both cases become

$$\left.\begin{aligned} u_0 &= \frac{(1-2\mu)Q}{16\pi Gc}\log\frac{(x-c)^2 + y^2}{(x+c)^2 + y^2}; \\ v_0 &= \frac{(1-2\mu)Q}{8\pi Gc}\left(\tan^{-1}\frac{x-c}{y} - \tan^{-1}\frac{x+c}{y}\right) \end{aligned}\right\} \quad [62]$$

$$\left.\begin{aligned} \sigma_{x0} &= \frac{(1-2\mu)Q}{2\pi}\left\{\frac{x^2 - y^2 - c^2}{(x^2 + y^2 + c^2)^2 - 4x^2c^2}\right\} \\ \sigma_{y0} &= -\sigma_{x0} \\ \tau_{xy0} &= \frac{(1-2\mu)Q}{\pi}\left\{\frac{xy}{(x^2 + y^2 + c^2)^2 - 4x^2c^2}\right\} \end{aligned}\right\} \quad [63]$$

and Equations [62] and [63] are also valid inside C for the loading on the line segment.

The Logarithmic Potential ϕ_0 as the Deflection of a Membrane

The function ϕ_0 as defined in Equation [18] may be looked upon as the deflection of a uniformly stretched membrane of circular form with a radius very large compared to the dimensions of the loaded area R.

Let A be the radius of the membrane, and assume it can be taken indefinitely large. Let ζ be the deflection of the membrane relative to its elevation at $r = A$ which is assumed constant.

If a concentrated force P is applied to the membrane at point x', y' situated a distance r' from the center, and if r'/A is very small, the slope of the membrane surface in the direction of lines projecting radially from P will be

$$\frac{\partial\zeta}{\partial\rho_0} = -\frac{P}{2\pi N\rho_0} \quad \ldots\ldots [64]$$

where ρ_0 is the distance from x', y' to the point x, y where $\partial\zeta/\partial\rho_0$ is evaluated, and N is the tension in the membrane.

From vertical-equilibrium Equation [64] we have

$$\zeta = -\frac{P}{2\pi N}\log\rho_0 + C \quad \ldots\ldots [65]$$

where C is a constant. If the deflection is zero on the boundary, and if A is indefinitely large, we will have

$$\zeta = -\frac{P}{2\pi N}\log\rho_0 + \frac{P}{2\pi N}\log A \quad \ldots\ldots [66]$$

For any distribution of pressure over a region R, every point of which is within a distance ϵ of the origin which is infinitesimal compared to A, ζ will be

$$\zeta = -\frac{1}{2\pi N}\int_R\int p\log\rho_0 dx'dy' + \frac{P}{2\pi N}\log A \quad [67]$$

in which P is the total load on R.

This expression will represent the deflection within an error that can be made smaller than any preassigned quantity by taking A sufficiently large compared to ϵ.

Introducing ϕ_0 as defined by Equation [18] we have the relations

$$\left.\begin{aligned} \zeta &= -\frac{1}{2\pi N}\phi_0 + \frac{P}{2\pi N}\log A \\ \phi_0 &= -2\pi N\zeta + P\log A \end{aligned}\right\} \quad \ldots\ldots [68]$$

$$\left.\begin{aligned} \text{grad}\,\phi_0 &= -2\pi N\,\text{grad}\,\zeta \\ \Delta\phi_0 &= -2\pi N\Delta\zeta = 2\pi p \end{aligned}\right\} \quad \ldots\ldots [69]$$

The slope of the membrane in a given direction when multiplied by $(1-2\mu)(N/2G)$ will therefore be analogous to the horizontal displacement in the surface of the elastic solid in that direction. The stresses can be expressed in terms of the second derivatives of ζ.

An Analogy Between Two- and Three-Dimensional Stress Systems for Semi-Infinite Bodies

Let the load on the semi-infinite elastic body be distributed with an intensity $q = f(x')$ along the line segment from $(-c, 0)$ to $(+c, 0)$ as shown in Fig. 11*a*.

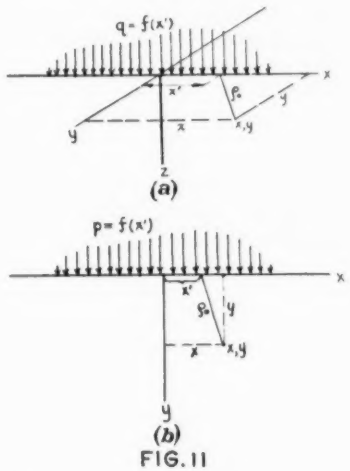

FIG. 11

The stresses in the surface will then be given by

$$\left.\begin{aligned} \sigma_{x0} &= -\frac{1-2\mu}{2\pi}\frac{\partial^2\phi_0}{\partial x^2}; \quad \sigma_{y0} = -\frac{1-2\mu}{2\pi}\frac{\partial^2\phi_0}{\partial y^2}; \\ \tau_{xy0} &= -\frac{1-2\mu}{2\pi}\frac{\partial^2\phi_0}{\partial x\partial y} \end{aligned}\right\} \quad [70]$$

$$\phi_0 = \int_{-c}^{c} f(x') \log \rho_0 \, dx' \quad [71]$$

If we have a semi-infinite solid in a state of plane strain loaded by pressure distributed along the band between $x = -c$ and $x = c$ with an intensity $p = f(x')$ as shown in Fig. 11*b* and if we take the x, z plane for the surface of the solid, the stresses in the interior will be

$$\left.\begin{aligned} \sigma_x &= \frac{1}{2\pi}\frac{\partial V}{\partial y} - \frac{y}{2\pi}\frac{\partial^2 V}{\partial x^2} \\ \sigma_y &= \frac{1}{2\pi}\frac{\partial V}{\partial y} - \frac{y}{2\pi}\frac{\partial^2 V}{\partial y^2} \\ \tau_{xy} &= -\frac{y}{2\pi}\frac{\partial^2 V}{\partial x\partial y} \end{aligned}\right\} \quad [72]$$

where

$$V = -2\int_{-c}^{c} f(x') \log \rho_0 \, dx' \quad [73]$$

The function V is simply the value taken by ψ, as defined in Equation [6], when the new orientation of the axes is used, one integration is carried out, and an infinite constant is dropped. The constant contributes nothing to the stresses.

Consider the shearing stress on 45-deg planes obtained by forming half the difference of σ_x and σ_y. Call this τ_{45}. This shearing stress, since $\Delta V = 0$, will be

$$\tau_{45} = -\frac{y}{2\pi}\frac{\partial^2 V}{\partial x^2} \quad [74]$$

We may now put down the following relations between the quantities in the plane-strain problem and those in the loaded-segment problem

$$V = -2\phi_0 \quad [75]$$

$$\left.\begin{aligned} \tau_{45} &= \frac{-2y}{1-2\mu}\sigma_{x0} = \frac{2y}{1-2\mu}\sigma_{y0} \\ \tau_{xy} &= \frac{-2y}{1-2\mu}\tau_{xy0} \end{aligned}\right\} \quad [76]$$

Therefore, if we know the shear stresses on 45-deg planes and on planes perpendicular to the x and y axes in the plane-strain problem, we will be able to calculate at once the stresses σ_{x0}, σ_{y0}, τ_{xy0} in the surface of a semi-infinite solid loaded along a line segment.

To illustrate this analogy, suppose we have a uniform load p_0 over the band between $x = -c$ and $x = c$ in the surface $y = 0$. The stresses will then be (8)

$$\left.\begin{aligned} \sigma_x &= -\frac{p_0}{2\pi}\left[2\left(\tan^{-1}\frac{x+c}{y} - \tan^{-1}\frac{x-c}{y}\right) + \frac{y(x-c)}{(x-c)^2+y^2} - \frac{y(x+c)}{(x+c)^2+y^2}\right] \\ \sigma_y &= -\frac{p_0}{2\pi}\left[2\left(\tan^{-1}\frac{x+c}{y} - \tan^{-1}\frac{x-c}{y}\right) - \frac{y(x-c)}{(x-c)^2+y^2} + \frac{y(x+c)}{(x+c)^2+y^2}\right] \\ \tau_{xy} &= \frac{p_0}{2\pi}\left[\frac{(x-c)^2-y^2}{(x-c)^2+y^2} - \frac{(x+c)^2-y^2}{(x+c)^2+y^2}\right] \end{aligned}\right\} \quad [77]$$

and we have

$$\tau_{45} = -\frac{p_0}{\pi}\left[\frac{y(x-c)}{(x-c)^2+y^2} - \frac{y(x+c)}{(x+c)^2+y^2}\right] \quad [78]$$

We therefore conclude that for the case of a uniform load q_0 per unit length along a line segment on the surface of a semi-infinite body, extending from $(-c, 0)$ to $(+c, 0)$

$$\left.\begin{aligned} \sigma_{x0} = -\sigma_{y0} &= \frac{(1-2\mu)}{2\pi} q_0 \left[\frac{x-c}{(x-c)^2+y^2} - \frac{x+c}{(x+c)^2+y^2}\right] \\ \tau_{xy0} &= -\frac{(1-2\mu)}{4\pi y} q_0 \left[\frac{(x-c)^2-y^2}{(x-c)^2+y^2} - \frac{(x+c)^2-y^2}{(x+c)^2+y^2}\right] \end{aligned}\right\} \quad [79]$$

An algebraic simplification shows that these expressions are identical with those given by Equations [63] when we put $q_0 = Q/2c$. Since the stresses in the surface due to the loaded line segment are the same as those for a rigid elliptical punch loading outside the loaded region, we can calculate the latter stresses at once if we know the stresses for the uniform load over a portion of the boundary for the case of plane strain.

This analogy holds equally well for a state of plane stress instead of plane strain. The loading on the edge of the plate will then be $pt = tf(x')$ per unit length, where t is the thickness of the plate.

Since photoelastic tests can be made to determine the shear stresses τ_{xy} and τ_{45} (it is only necessary to observe the principal stress difference and the orientation) the way is open to the evaluation of the stresses in the surface for loading along a line segment by means of plane stress photoelastic tests.

SUMMARY

I There are a number of cases in which an infinite variety of loadings inside a region R give rise to the same stresses and horizontal displacements in the surface outside R. Cases investigated are shown in Fig. 12.

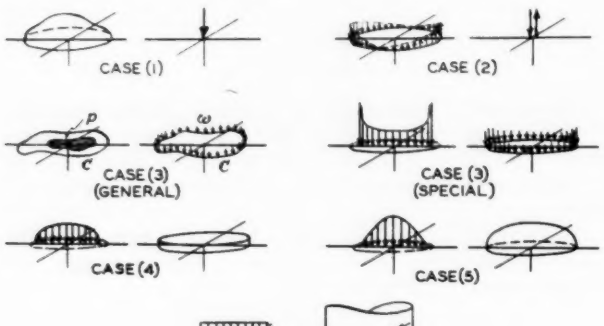

FIG. 12

II The analogy between the logarithmic potential ϕ_0 due to the loading on the solid and the deflection ζ of a large circular membrane with the same loading states that

$$\phi_0 = -2\pi N\zeta + P \log A$$

III Shear stresses τ_{xy} and τ_{45} in the plane strain problem of the semi-infinite body with loading $p = f(x')$ on the surface $y = 0$ are analogous to stresses τ_{xy0} and σ_{x0} (or $-\sigma_{y0}$) in the surface $z = 0$ of a semi-infinite solid with loading $q = f(x')$ along the x-axis. The latter quantities are multiplied by the factor $-2y/(1 - 2\mu)$.

Appendix

If R is a region in the finite part of the plane $z = 0$, and if two different source distributions $p = f(x', y')$ and $p_1 = f_1(x', y')$ in R give rise to logarithmic potentials

$$\phi_0 = \int_R\int p \log \rho_0 dx'dy' \quad [80]$$

$$\phi_{01} = \int_R\int p_1 \log \rho_0 dx'dy' \quad [81]$$

such that outside R

$$\text{grad } \phi_0 = \text{grad } \phi_{01} \quad [82]$$

then we can say that $\phi_0 = \phi_{01}$ everywhere outside R. For, by Gauss's theorem, if B be any closed curve outside of and surrounding R

$$\oint_B \text{grad}_n \phi_0 ds = \oint_B \text{grad}_n \phi_{01} ds = 2\pi \int_R\int p dx'dy' = 2\pi \int_R\int p_1 dx'dy' \quad [83]$$

and the total loads in R in both cases will be alike and equal to P. If there is any difference between ϕ_0 and ϕ_{01} outside R, they will differ by an additive constant, by virtue of hypothesis of Equation [82]. But since the loadings in both cases are of the same total amount we have

$$\left.\begin{aligned} \lim_{r\to\infty} (\phi_0 - P \log r) &= 0 \\ \lim_{r\to\infty} (\phi_{01} - P \log r) &= 0 \end{aligned}\right\} \quad [84]$$

which is impossible if ϕ_0 differs from ϕ_{01} by a constant. Hence ϕ_0 must equal ϕ_{01} everywhere outside R. This proposition is useful because it reduces the problem of proving two logarithmic potential functions, Equations [80] and [81], equal to that of proving that their gradients are equal.

We will now amplify the treatment of the different cases of loading producing the same stresses and horizontal displacements in the surface outside the loaded area.

Case I. Consider the loading $p = f(r')$ on the circle of radius a. Applying Gauss's theorem in two-dimensional form of Equation [24] to a circle outside $r = a$ and of radius r we get

$$2\pi r \frac{\partial \phi_0}{\partial r} = 2\pi P \quad [85]$$

$$\frac{\partial \phi_0}{\partial r} = \frac{P}{r} \quad [86]$$

But this is the same as the radial component of the gradient due to the concentrated force P at the origin. The tangential component of the gradient is zero in both cases by radial symmetry. Hence, for $r > a$ in both cases the gradients of the logarithmic potentials are alike and the potentials themselves are alike and equal to

$$\phi_0 = P \log r \quad [87]$$

and the stresses and horizontal displacements are easily calculated by Equations [26] and [27] and shown to be the expressions given by Equations [29] and [30].

The stresses inside the loaded area can also easily be found for the case of the loaded circle. Again, by Gauss's theorem, for $r<a$

$$2\pi r \frac{\partial \phi_0}{\partial r} = 2\pi \int_0^r 2\pi r' f(r') dr' = 2\pi P_r \quad [88]$$

$$\frac{\partial \phi_0}{\partial r} = \frac{P_r}{r} \quad [89]$$

$$\frac{\partial^2 \phi_0}{\partial r^2} = 2\pi p - \frac{P_r}{r^2} \quad [90]$$

so that the horizontal displacements and stresses will be

$$\delta_{r0} = -\frac{1-2\mu}{4\pi G} \cdot \frac{P_r}{r}; \quad \delta_{\theta 0} = 0 \quad [91]$$

$$\left.\begin{aligned} \sigma_{r0} &= -p + \frac{1-2\mu}{2\pi} \frac{P_r}{r^2}; \quad \sigma_{z0} = -p \\ \sigma_{\theta 0} &= -2\mu p - \frac{1-2\mu}{2\pi} \frac{P_r}{r^2}; \quad \tau_{r\theta 0} = 0 \end{aligned}\right\} \quad [92]$$

Outside the circle $r = a$ we have $P_r = P$ and $p = 0$ so that Equations [29] and [30] are particular cases of Equations [91] and [92].

Comparing the stresses just inside the circle of radius a with those just outside, we see that there is a discontinuity in σ_{r0} at $r = a$ of amount p_a, the pressure at $r = a$, and a discontinuity in $\sigma_{\theta 0}$ of amount $2\mu p_a$.

The vertical displacements of the surface will not be alike for the two cases of loading. For the loaded circle

$$w_0 = \frac{1-\mu}{2\pi G} \int_0^a \int_0^{2\pi} \frac{f(r')r'dr'd\theta'}{\rho_0} \quad [93]$$

while for the concentrated load

$$w_0 = \frac{1-\mu}{2\pi G}\frac{P}{r} \quad \ldots\ldots\ldots\ldots\ldots\ldots [94]$$

If the pressure distribution in the circle is such that $p = 0$ for $r < b$ and $p = f(r')$ for $b < r < a$, the stresses and horizontal displacements would be zero inside the ring.

Case II. The equivalence of the logarithmic potentials outside the circle of radius a for the loadings shown in Figs. 5*a* and 5*b* can be demonstrated as follows.

Let P be a downward force at $x = c$, $y = 0$ and $-P$ be an upward force at $x = -c$, $y = 0$. Let $P = m/2c$. Now if we allow c to approach zero, keeping m constant we obtain the concentrated couple of Fig. 5*b*. The potential due to force P will be equal to the potential due to a uniform pressure $p_0 = P/\pi a^2$ over a circle of radius a and center at $(+c, 0)$. The potential due to force $-P$ will be equal to that due to pressure $-p_0$ over a circle of radius a with center at $(-c, 0)$. As c is allowed to approach zero the circles overlap and their loads cancel except for semicircular crescent-shaped regions on either side of the y-axis. The loading on the crescent on the side $x > 0$ is p_0 and the loading on the other crescent is $-p_0$ per unit area. When c becomes very small, the width of the crescent region becomes

$$t = 2c\cos\theta' \quad \ldots\ldots\ldots\ldots\ldots\ldots [95]$$

and the load per unit length around the circle $r = a$, becomes in the limit as $c \to 0$

$$\omega = \lim_{c\to 0} p_0 t = \lim_{c\to 0} \frac{m}{2c}\frac{1}{\pi a^2} 2c\cos\theta' \quad \ldots\ldots\ldots [96]$$

$$\omega = \frac{m}{\pi a^2}\cos\theta'$$

Since the potential due to the loaded circles was at all times equal to the potential due to the forces P and $-P$ during this process, in the limit the potential due to the ω loading becomes equal to the potential due to the concentrated couple m, for the region outside the circle $r = a$. The logarithmic potential of a plane doublet of moment m is well known and is given by the first of Equations [32]. The horizontal displacements and stresses are easily obtained from ϕ_0.

Inside the circle of radius a for the loading of Fig. 5*a* the potential gradient may be calculated by a similar type of reasoning and found to be

$$\frac{\partial\phi_0}{\partial r} = -\frac{m\cos\theta}{a^2};\quad \frac{\partial\phi_0}{r\partial\theta} = \frac{m\sin\theta}{a^2} \quad \ldots\ldots\ldots [97]$$

The stresses in the surface are zero inside the circle $r = a$. There is a discontinuity in $\partial\phi_0/\partial r$ at $r = a$ of amount $2\pi\omega$ as would be anticipated by Equation [25].

The vertical displacements are not alike for the two cases of loading, being

$$w_0 = \frac{1-\mu}{2\pi G}\frac{m\cos\theta}{r^2} \quad \ldots\ldots\ldots\ldots [98]$$

for the concentrated couple, and

$$w_0 = \frac{1-\mu}{2\pi G} m\cos\theta\left[\frac{2(r+a)}{\pi r a^2}\left\{\frac{r^2+a^2}{(r+a)^2}F'(n) - E'(n)\right\}\right] \quad [99]$$

for the ω loading on the circle, where n is the number

$$n = \frac{2\sqrt{ra}}{r+a}$$

and F' and E' are the complete elliptic integrals of first and second type; symbols K and E are sometimes used, as by Peirce (9). Since w_0 for the ω loading varies as the product of $\cos\theta$ with a function of r, points on a circle $r =$ constant will remain in a plane after the vertical displacements have taken place.

Case III. Here we had $p(x',y')$ as a source distribution in a region R' and C a closed curve around R' and outside it as shown in Fig. 6*a*. Let the value of ϕ_0 due to the sources p be ϕ_{0c} on C and not necessarily constant along this curve. Now it is possible to find one and only one source distribution ω along C such that the logarithmic potential due to sources ω is equal to ϕ_{0c} on C and equal to ϕ_0 outside C, and this source distribution is the one defined by Equation [35]. This constitutes the two-dimensional statement of a proposition in potential theory due to Green (10). The proof that the potential due to sources ω on C is actually ϕ_0 outside C may be outlined as follows.

Let the potential due to sources ω be V. Then, by definition of ω and V

$$V = \frac{1}{2\pi}\oint_C \log\rho_0\left(\frac{\partial\phi'}{\partial n_1} - \frac{\partial\phi'}{\partial n_2}\right)ds \quad \ldots\ldots [100]$$

where ρ_0, as usual, is the distance from a point x',y' on C to the point x,y where V is to be evaluated. Noting that $\partial\phi'/\partial n_1 = \partial\phi_0/\partial n_1$ since $\phi' = \phi_0$ outside C, we have, by Green's transformation (11)

$$V = \frac{1}{2\pi}\left[\oint_C\left(\phi_0\frac{\partial}{\partial n_1}\log\rho_0 - \phi'\frac{\partial}{\partial n_2}\log\rho_0\right)ds - \int_R\int\{\phi_0\,\Delta\log\rho_0 - \phi'\Delta\log\rho_0 - \log\rho_0(\Delta\phi_0 - \Delta\phi')\}dA\right] \quad [101]$$

The line integral vanishes since $\phi_0 = \phi' = \phi_{0c}$ on C, and the normal derivative of $\log\rho_0$ is continuous from one side of C to the other. In the integral over R all terms except $\Delta\phi_0\log\rho_0$ are zero. Therefore

$$V = \frac{1}{2\pi}\int\int_R \Delta\phi_0\log\rho_0 dA \quad \ldots\ldots\ldots [102]$$

But $\Delta\phi_0$ is $2\pi p$ where p is the source intensity in R' giving rise to ϕ_0, and consequently

$$V = \int_{R'}\int p\log\rho_0 dA \quad \ldots\ldots\ldots\ldots [103]$$

But this is precisely ϕ_0. Therefore, the sources ω on C give rise to potential ϕ_0 outside C. Inside C, for the source distribution ω, we will have $\Delta V = 0$ and V takes the value ϕ_{0c} on C. Hence $V = \phi'$ inside C, since Laplace's equation has a unique solution in a region when the value around the boundary is given.

The loading ω defined by Equation [38] is the one which makes the ellipse C on which it is applied an equipotential curve. We are guided in the treatment of this problem by the well-known theory of the electric potential due to a charged ellipsoidal conductor (12). When the ellipsoid is made infinitely long it becomes an elliptical cylinder. The electric charge distributes itself on the surface so as to make this surface one of constant potential. When the elliptic coordinates λ, ν are used to describe the potential field it is at once evident that the potential is linearly related to λ, since λ is a harmonic function of x and y and therefore fulfills the requirement for the potential outside the charged cylinder and since λ is constant on the charged surface.

In the first of Equations [43], for ϕ_0, the term $-\log 2/c$ is introduced so as to make the potential approach $Q\log r$ at an infinite

distance. The source distribution ω on C is obtained by applying Equation [25], noting that $\partial\phi_0/\partial n_2$ is zero since ϕ_0 is constant within the ellipse. This gives us

$$\omega = \frac{1}{2\pi} Q \operatorname{grad} \lambda = \frac{Qh}{2\pi} \quad [104]$$

Expressing h in terms of rectangular coordinates x', y' of a point on the ellipse we obtain the distribution given by Equation [38].

Since λ is a function of x, y and the focal distance c, the potential given by the first of Equations [43] will be the one corresponding to a source distribution ω around any ellipse having foci $(-c, 0)$, $(+c, 0)$. We can state that all confocal ellipses carrying a source distribution given by Equation [38] will produce the same potential in the region external to all, when the total source strength is the same in all cases. The smallest one of such confocal ellipses is an infinitely narrow one which coincides with the line segment between the common foci. The loading per unit length on this line segment will be

$$q = \lim_{\substack{b \to 0 \\ a \to c}} 2\omega = \frac{Q}{\pi c \sqrt{[1 - (x'^2/c^2)]}} \quad [105]$$

The q loading on the line segment given by Equation [37] thus produces the same potential outside C as the ω loading on C given by Equation [38].

In connection with the discussion of the elliptical ring having C as its outer boundary, the width of this ring may be shown to be

$$t = \frac{k}{\sqrt{\left(\frac{x'^2}{a^4} + \frac{y'^2}{b^4}\right)}} \quad [106]$$

so that the load per unit length, $p_0 t$, is

$$p_0 t = \frac{Qt}{2\pi abk} = \frac{Q}{2\pi ab\sqrt{\left(\frac{x'^2}{a^4} + \frac{y'^2}{b^4}\right)}} = \omega \quad [107]$$

The width of the ring t at point x',y' is the product of k and the distance from the origin to the tangent line to C at x',y', as may be seen by geometrical reasoning. The distance to the tangent line is

$$\frac{1}{\sqrt{\left(\frac{x'^2}{a^4} + \frac{y'^2}{b^4}\right)}} \quad [108]$$

so that we see the loading ω is distributed around C proportionately to this distance.

Case IV. The proposition here stated, that any two confocal ellipses having uniform source distributions over their areas give rise to the same logarithmic potential in the region external to both if the totals of the sources on them are alike, is the two-dimensional form of Maclaurin's theorem (13). This theorem states that two homogeneous, solid, confocal ellipsoids of the same total mass produce the same gravitational attraction (and potential) in the region external to both. One may prove the two-dimensional form of this theorem either by first establishing it for ellipsoids and then choosing the ellipsoids infinitely long, or else by starting at the beginning and reconstructing the proof for the two-dimensional case. We will not go into the proof here, though it is of theoretical interest and not difficult.

The two-dimensional problem of calculating the logarithmic potential due to a uniform source distribution over an elliptical disk is the same as that of calculating the Newtonian potential due to an infinitely long elliptical cylinder. This problem is most easily handled by first obtaining the expression for the potential of a solid homogeneous ellipsoid (13) and then allowing one axis of the ellipsoid to increase indefinitely. In this way we find that the logarithmic potential of the uniformly loaded ellipse is

$$\phi_0 = -\frac{1}{2}(V - V_A - 2p_0 \pi ab \log A) \quad [109]$$

where A is a distance r that increases without limit and

$$V = \pi abp_0 \int_\gamma^\infty \frac{\left(1 - \frac{x^2}{c^2 + u} - \frac{y^2}{u}\right) du}{\sqrt{[u(c^2 + u)]}} \quad [110]$$

and γ, given in Equation [53], is the positive root of the equation

$$\frac{x^2}{c^2 + \gamma} + \frac{y^2}{\gamma} = 1 \quad [111]$$

The function V is the Newtonian potential of an infinitely long elliptical cylinder of density p_0. The integral in Equation [110] can be evaluated without difficulty and, for external points, we find

$$\phi_0 = \frac{\pi ab}{2} p_0 \left[\log \frac{\sqrt{\gamma(c^2 + \gamma)} + \gamma + (c^2/2)}{2} + \frac{2x^2}{c^2}\left(1 - \sqrt{\frac{\gamma}{c^2 + \gamma}}\right) - \frac{2y^2}{c^2}\left(1 - \sqrt{\frac{c^2 + \gamma}{\gamma}}\right)\right] \quad [112]$$

For large values of $x^2 + y^2$ we find that ϕ_0 approaches $\pi abp_0 \log \sqrt{(x^2 + y^2)}$ as it should. The constants in Equation [109] were chosen for this purpose. For points inside the ellipse we take $\gamma = b^2$ in evaluating the integral Equation [110] and obtain

$$\phi_0 = \frac{\pi ab}{2} p_0 \left[\log \frac{(a + b)^2}{4} + \frac{2x^2}{c^2}\left(1 - \frac{b}{a}\right) - \frac{2y^2}{c^2}\left(1 - \frac{a}{b}\right)\right] \quad [113]$$

From Equation [112] the gradient of ϕ_0 can be easily calculated and Equations [51] and [52] are derived. For points inside the loaded ellipse the gradient is calculated from Equation [113] and the horizontal displacements and stresses become

$$u_0 = -\frac{1 - 2\mu}{2\pi G}\left(\frac{Qx}{a(a + b)}\right); \quad v_0 = -\frac{1 - 2\mu}{2\pi G}\left(\frac{Qy}{b(a + b)}\right) \quad [114]$$

$$\left.\begin{aligned} \sigma_{x0} &= -2\mu p_0 - \frac{1 - 2\mu}{\pi a}\frac{Q}{(a + b)} \\ \sigma_{y0} &= -2\mu p_0 - \frac{1 - 2\mu}{\pi b}\frac{Q}{(a + b)} \\ \tau_{xy0} &= 0 \\ \sigma_{z0} &= -p_0 \end{aligned}\right\} \quad [115]$$

Inside the ellipse, therefore, σ_{x0}, σ_{y0}, σ_{z0} are the principal stresses and they are constant everywhere over the elliptical area. The resultant horizontal displacement $\sqrt{(u_0^2 + v_0^2)}$ is constant around ellipses geometrically similar to C.

The stresses are discontinuous at the edge of the loaded ellipse. For, as the ellipse is approached from the outside the stresses become, by Equation [52]

$$\sigma_{x0} = \frac{1 - 2\mu}{\pi c^2} Q\left(\frac{ab^3}{b^4 + y^2c^2} - 1\right); \quad \sigma_{y0} = -\sigma_{x0};$$

$$\tau_{xy0} = \frac{1 - 2\mu}{\pi} Q\left(\frac{xyb}{a(b^4 + y^2c^2)}\right) \quad [116]$$

Case V. In this case we compared the semiellipsoidal loading of Fig. 9*b* with the parabolic loading on a line segment between the foci of the loaded ellipse, as shown in Fig. 9*a*.

That these two load distributions produce the same logarithmic potential outside C may be shown by dividing the semiellipsoidal loading into a number of uniformly loaded elliptical areas, as indicated in Fig. 9*b*, each carrying a pressure dp. A typical one of these elements would be the ellipse of semiaxes $a\sqrt{[1-(p^2/p_0^2)]}$ and $b\sqrt{[1-(p^2/p_0^2)]}$ with foci at $x = \pm c', y = 0$ where $c' = c\sqrt{[1-(p^2/p_0^2)]}$. By the proposition of case IV, the potential due to this element will be equal, outside it and hence outside C, to the potential due to loading dq per unit length along the line segment from $(-c', 0)$ to $(+c', 0)$ which varies as

$$dq = \frac{2dQ}{\pi c'}\sqrt{\left(1-\frac{x'^2}{c'^2}\right)} \quad \ldots\ldots\ldots\ldots [117]$$

where dQ is the total load on the element, given by

$$dQ = \pi abdp[1-(p^2/p_0^2)] \quad \ldots\ldots\ldots\ldots [118]$$

When the elemental ellipse with load dp has a focal distance equal to x', the magnitude dq of the semielliptical load corresponding to it at x' is zero. All of the elliptical elements smaller than this one will have corresponding semielliptical loadings which do not extend as far as x'. Consequently, the load on the line segment corresponding to the full semiellipsoidal loading will have magnitude at x' given by

$$q(x') = \frac{2}{\pi}\int_0^{\bar{p}} \frac{dQ}{c'}\sqrt{\left(1-\frac{x'^2}{c'^2}\right)} = \frac{\pi abp_0}{2c}\left(1-\frac{x'^2}{c^2}\right). [119]$$

where

$$\bar{p} = p_0\sqrt{[1-(x'^2/c^2)]}$$

Here $\bar{p}$ is the value of p for which the corresponding elliptical element has focal distance $c' = x'$.

The logarithmic potential due to both cases of loading is found by direct integration, using the parabolic loading on the line segment rather than the semiellipsoidal loading, to simplify the integration.

The vertical displacements in the surface are different in the two loadings. For the semiellipsoidal loading we have inside C

$$w_0 = \frac{3(1-\mu)}{4\pi G}\frac{Q}{a}\left[F'\left(\frac{c}{a}\right) - \frac{x^2}{c^2}\left\{F'\left(\frac{c}{a}\right) - E'\left(\frac{c}{a}\right)\right\} - \frac{y^2}{c^2}\left\{\frac{a^2}{b^2}E'\left(\frac{c}{a}\right) - F'\left(\frac{c}{a}\right)\right\}\right] \ldots [120]$$

and outside C

$$w_0 = \frac{3(1-\mu)}{4\pi G}\frac{Q}{a}\left[F\left(\alpha,\frac{c}{a}\right) - \frac{x^2}{c^2}\left\{F\left(\alpha,\frac{c}{a}\right) - E\left(\alpha,\frac{c}{a}\right)\right\} - \frac{y^2}{c^2}\left\{\frac{a^2}{b^2}E\left(\alpha,\frac{c}{a}\right) - F\left(\alpha,\frac{c}{a}\right) - \frac{a}{\sqrt{(\gamma-b^2)}}\left(\frac{a^2}{b^2}\sqrt{\frac{\gamma}{c_2+\gamma}} - \sqrt{\frac{c_2+\gamma}{\gamma}}\right)\right\}\right] .. [121]$$

where $\alpha = \cot^{-1}\sqrt{[(\gamma-b^2)/a^2]}$ and γ is as defined in Equations [53] and [111]. We see that inside C the deformed surface is an elliptical paraboloid. The evaluation of the integrals involved outside C is due to V. A. Hoersch (14).

The displacement w_0 for the parabolic loading is

$$w_0 = -\frac{(1-\mu)}{4G}\cdot\frac{p_0ab}{c^2}\left\{\left(c^2-x^2+\frac{y^2}{2}\right)\right.$$

$$\times \log\frac{x-c+\sqrt{[(x-c)^2+y^2]}}{x+c+\sqrt{[(x+c)^2+y^2]}} + \frac{3x+c}{2}\sqrt{[(x-c)^2+y^2]} - \frac{3x-c}{2}\sqrt{[(x+c)^2+y^2]}\left.\right\} .. [122]$$

Case VI. The validity of the statement that both types of loading shown in Figs. 10*a* and 10*b* in this case produce the same logarithmic potential in the region outside C can be shown by dividing the loaded elliptical area into elliptical rings bounded by geometrically similar ellipses. The pressure on any one of these rings will be uniform around its periphery and will produce the same logarithmic potential outside C as a loading on a line segment of the type discussed in case III. Superimposing all such segment loadings corresponding to all the loaded ring elements we obtain the uniformly loaded line segment of Fig. 10*a*. The logarithmic potential due to this loaded segment may be easily calculated. The vertical displacements w_0 are different for the two types of loading. For the line-segment loading

$$w_0 = \frac{1-\mu}{2\pi G}\frac{Q}{c}\coth^{-1}\frac{\sqrt{(c^2+\gamma)}}{c} \quad \ldots\ldots\ldots [123]$$

while for loading applied by the rigid punch we obtain, outside C

$$w_0 = \frac{1-\mu}{2\pi G}\frac{Q}{a}F\left(\alpha,\frac{c}{a}\right) \quad \ldots\ldots\ldots\ldots [124]$$

and within C $\quad w_0 = \frac{1-\mu}{2\pi G}\cdot\frac{Q}{a}F'\left(\frac{c}{a}\right) = \text{const.} \quad \ldots\ldots\ldots [125]$

At a great distance from the origin Equations [123] and [124] both approach $[(1-\mu)/2\pi G]\cdot(Q/r)$ asymptotically. Since α depends on γ and since the curves $\gamma = \text{constant}$ are confocal ellipses we see that for both types of loading the surface deflection is constant around ellipses confocal with C.

Forty-Eight Ordinate Harmonic Analysis and the Harmonic Spectrum of Two-Cycle Diesel Torque

By NANCY KLOCK,[1] EAST HARTFORD, CONN.

For the harmonic analysis of periodic curves, machines as well as numerical methods are available. The machines are expensive and not generally available, and time is required to learn their operation. Therefore, an occasional analysis of a curve consumes even less time by the numerical method than by the machine. The best known numerical method is that of Runge (1)[2] described in many places; a good account is found in Scarborough's book (2). The principle is clear, but writers usually give the method for 6, 12, or 24 ordinates for the sake of simplicity, which is not sufficiently accurate for most applications. In this paper the 48-ordinate scheme is fully given in Tables 1, 2, and 3.

For the analysis of torsional vibrations the harmonic content of the torque curve of the disturbing engine is required. Such analyses have been published for the four-cycle Diesel engine (3) and for the four-cycle gasoline engine for aviation purposes (4). But to the author's knowledge none have been published for the two-cycle Diesel engine. Such a spectrum is given herein.

OCCASIONALLY it is found desirable to determine the high-order Fourier harmonics present in a repeating curve. A simple numerical method to obtain orders as high as desired has been worked out by Runge (1). Scarborough (2) gives an excellent description of the general method together with a complete scheme for 24 ordinates which allows the determination of the first 12 harmonics. For most cases the accuracy obtainable is insufficient. Other numerical methods for special purposes have been proposed by Lewis (3) and Zipperer (5).

When higher harmonics, or better accuracy in the lower ones, are wanted, more than 24 ordinates from the original curve must be chosen. If the ordinates at 48 equally spaced abscissas are taken, the constant term and 23 sine and 24 cosine components can be obtained. This article is primarily intended to make available a simple procedure by which from 15 to 20 harmonics can be computed quite accurately, the remaining high harmonics becoming less accurate. Since Runge's method has been well described in several articles and books (2), his theory will not be repeated in this paper, but only the procedure itself is described.

To simplify the description of the procedure, it is applied to a specific case. An indicator card, supplied by the Busch-Sulzer Bros. Diesel Engine Co., has been converted to a curve of torque versus crank angle, as shown in Fig. 1. The torque magnitude is given in arbitrary units and the harmonics are later converted to per cent of mean torque which is represented by the dotted line in the figure. From this curve the values of the torque harmonics with respect to engine speed are computed as follows:

1 The 360-deg cycle is divided into 48 equal parts, that is, into 7.5-deg intervals. The ordinates at these divisions are called $y_0, y_1, y_2, \ldots y_{47}$, corresponding to $\omega t = 0, 7.5, 15, \ldots 352.5$ deg, respectively. The y values, including signs, must then be placed in the second and third rows of Table 1 in the order indicated by the printed numbers of the first row in this table. (At this point it should be noted that y_{24}, at the mid-point of the cycle, is placed at the beginning of the third row and y_{25} is then placed under y_{23} at the end of the row, etc.)

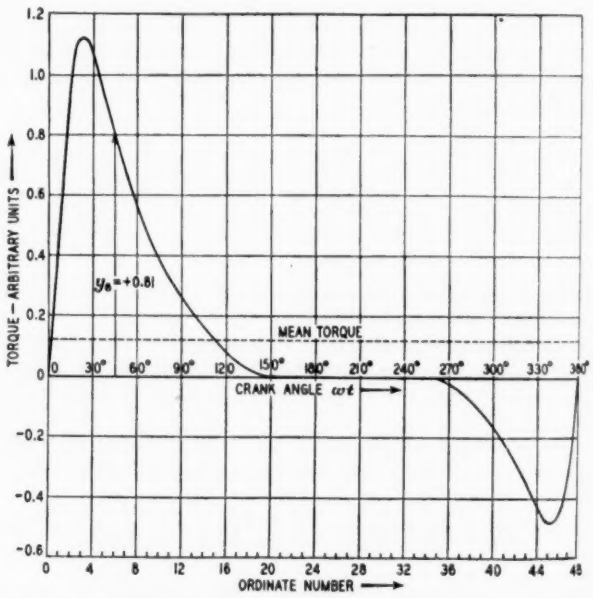

FIG. 1 TORQUE CURVE OF A TWO-CYCLE DIESEL ENGINE
(The torque values have been obtained from an indicator card supplied by Busch-Sulzer Bros. Diesel Engine Company. The values are for full-load conditions.)

2 Adding algebraically $(y_0 + y_{24})$, $(y_1 + y_{47})$, $(y_2 + y_{46})$, $\ldots$ $(y_{23} + y_{25})$, the values for the sums $c_0, c_1, c_2, \ldots c_{23}$ are then placed in the fourth row of this table. Subtracting algebraically, $(y_0 - y_{24})$, $(y_1 - y_{47})$, $(y_2 - y_{46})$, $\ldots$ $(y_{23} - y_{25})$, similar values for the difference terms d are found and placed in the fifth row. This completes the first part of Table 1.

3 The values of c_0 through c_{23} are then copied in the second rectangle on the left, those for d_0 through d_{23} in the second rectangle on the right. The addition and subtraction procedure is now repeated, resulting in e and f terms from the c's, and g and h terms from the d's.

[1] Engineer, Hamilton Standard Propeller Company.

[2] Numbers in parentheses refer to the Bibliography at the end of the paper.

Presented at the National Meeting of the Applied Mechanics Division, Ann Arbor, Mich., June 20–21, 1940, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 10, 1941, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

4 The remaining computations in Table 1 are similarly filled in as directed.

5 The values A_1 (= sin 7½ deg), A_2 (= sin 15 deg), ... A_{11} (= sin 82½ deg), are included in Table 1, making the sheet complete with all the information necessary for further work in the determination of the desired harmonics.

6 The remaining procedure is equally simple. Tables 2 and 3 give the values for the sine and cosine components of each frequency and by substituting values from Table 1 into these equations, the sine terms (a_1 through a_{23}) and cosine terms (b_0 through b_{24}) can be found. These are the coefficients which go into the Fourier series

$$f(\omega t) = b_0 + b_1 \cos \omega t + b_2 \cos (2\,\omega t + \phi_2) + \ldots\ldots + b_{24} \cos(24\,\omega t + \phi_{24}) + a_1 \sin \omega t + a_2 \sin (2\,\omega t + \phi_2) + \ldots\ldots + a_{23} \sin (23\,\omega t + \phi_{23})$$

As an example take the ninth harmonic

$$24\,a_9 = -(1.49 - 0.280) - 0.383\,(+ 2.325) + 0.707\,(+ 1.945) + 0.924\,(+ 1.045) = + 0.240$$

$$24\,b_9 = + (0 - 0.340) + 0.383\,(- 0.475) - 0.707\,(- 0.155) - 0.924\,(- 0.005) = - 0.408$$

so that $a_9 = + 0.0100$ and $b_9 = - 0.0170$, both in the arbitrary units chosen. The value found for b_0 in these units

$$\frac{1}{48}\,(p_0 + p_1 + p_2) = \frac{1}{48}\,(+ 1.895 + 1.785 + 2.095) = + 0.1203$$

represents the mean torque, and the sine and cosine functions, in per cent of this mean value, are respectively

a_9 = 8.3 per cent of mean torque
b_9 = 14.1 per cent of mean torque

$$24\,b_{24} = + q_0 - p_1 + p_2$$

7 The absolute magnitude of each frequency in this series is then obtained by adding the squares of the sine and cosine components for this 9th order torque:

$$T_9 = \sqrt{(8.3^2 + 14.1^2)} = 16 \text{ per cent of mean torque}$$

In this manner the other torque harmonics present in the two-cycle Diesel engine have been computed and these values are represented by the solid curve of Fig. 2. The values are given

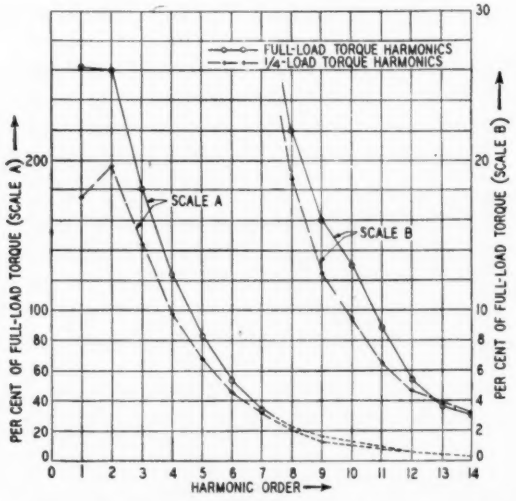

FIG. 2 TORQUE HARMONICS PRESENT IN A TWO-CYCLE BUSCH-SULZER DIESEL ENGINE

up through the 14th order, in terms of the full-load mean torque. As mentioned previously, the procedure herein described gives very good accuracy for the harmonics up to about the twentieth, while the still higher ones become unreliable.

The indicator card from which these harmonic torques were determined was for one of six cylinders under full-load conditions. The dashed line of Fig. 2 is the result of a similar analysis for half indicated power; because of internal friction, the brake horsepower for this condition is about one fourth the full-load brake horsepower. The ordinates for this harmonic curve are, as before, in per cent of full-load torque, not of mean quarter-load torque.

It is interesting to note that the peak pressure at half indicated power is about 10 per cent lower than the peak pressure at full load and that the harmonic disturbances are less by a similar order of magnitude in spite of the fact that the mean torque has been halved.

ACKNOWLEDGMENT

The author is greatly indebted to J. P. Den Hartog of Harvard University for his suggestions and invaluable assistance in the preparation of this paper.

Turbine-Blade Vibration Due to Partial Admission

By R. P. KROON,[1] PHILADELPHIA, PA.

This paper deals with stresses in steam-turbine blades set up during partial admission, that is, when the steam loading on the blades is intermittent. By making simplifying assumptions about the character of the loading, it is possible to develop simple relations showing how the blade stress depends on frequency, running speed, and damping. Apparatus to determine experimentally the damping of blade steels and optical equipment to investigate the exact nature of the steam forces acting on the blades in actual operation are described.

THE term "partial admission" is used whenever steam is admitted to the rotating blades of a turbine over only a portion of the periphery. Fig. 1 illustrates this type of steam flow. It shows a single wheel propelled by a steam jet emerging from a series of nozzles, covering but a small part of the circumference.

Partial admission has been applied since the earliest days of the steam turbine. Because it produces high turbine efficiency at low loads, it has been used on units of all sizes. However, the use of partial admission on large high-pressure high-temperature machines has created an industry-wide problem of shroud and blade failures.

The blades, passing through the steam jet every revolution, are loaded intermittently. The general character of the force acting on the blades is represented in Fig. 2. In this figure the force is plotted as a function of time, or as a function of distance traveled by the blade, during one revolution of the rotor spindle.

First occurs a period in which the blade, entering the nozzle jet, is subjected to variable steam forces before steady flow through the blade passages on either side of the blade is established.

During the following or second period, the force on the blade is substantially constant, except for some slight periodic variations caused by wakes in the steam flow behind the nozzle vanes.

The third period corresponds to the blade leaving the steam jet.

As they rotate, the blades are subjected to a variable loading such as shown in Fig. 2 once every revolution. If the conditions are such that the steam forces in the first and third periods are for a major part in phase with the blade velocity, energy is fed into the blade system continuously and large vibratory motions with high stresses result.

Vibratory Conditions of Blades

It will be advantageous to examine first the vibratory conditions of blades with the simplest possible loading diagram, shown in Fig. 3.

In design, it is of special interest to know the maximum amplitudes of vibration which can exist for a given steam force P_0. Considering the type of loading shown in Fig. 3 to be a series of successive instantaneous loadings and unloadings, it is obvious from energy considerations that maximum motion will result as the load is applied when the blade is in its extreme backward position, and removed when the blade is in its extreme forward position. Actually the timing of the steam-jet loading with respect to the blade motion is hard to predict accurately because there are a large number of vibration cycles, say, between 20 and 60 for every revolution.

Fig. 4 shows the motions of blade with a single steam jet and with the worst possible timing of the load. In the following, the blades are considered as having a single degree of freedom so that at all times amplitude and stress are proportional. Let y_{st} be the static deflection of the blade under the force P_0 and let there be n cycles of vibration per revolution, n being an integer. Let there be n_2 cycles in the loaded period and n_1 cycles in the unloaded portion of the revolution. For maximum amplitudes n_2 should be equal to any integer $+1/2$.

A sudden application of the load is equivalent to a shift of the neutral point about which the vibration takes place. With δ being the logarithmic decrement, the various amplitudes, shown in Fig. 4, are related as follows

$$b = a + y_{st}$$
$$c = b e^{-n_2\delta}$$
$$d = c + y_{st}$$
$$a = d e^{-n_1\delta}$$

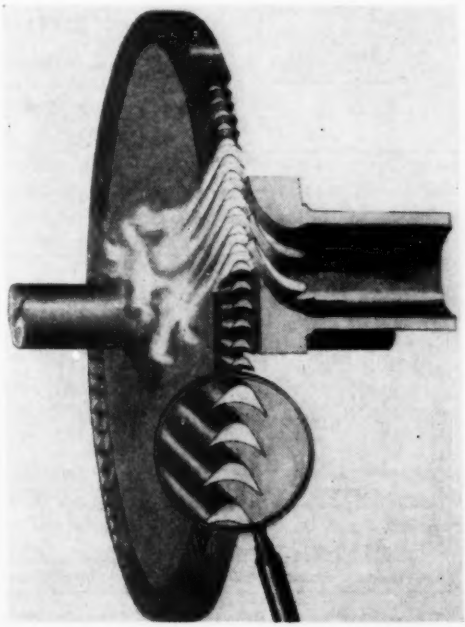

Fig. 1 Turbine Wheel Operating With Partial Admission

[1] Manager Experimental Division, Westinghouse Electric & Manufacturing Company, South Philadelphia Works. Jun. A.S.M.E.

Presented at the National Meeting of the Applied Mechanics Division, Ann Arbor, Mich., June 20–21, 1940, of The American Society of Mechanical Engineers.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 10, 1941, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

These equations are sufficient to solve for the unknown amplitudes a, b, c, and d. For example

$$b = y_{st}\frac{1 + e^{-n_1\delta}}{1 - e^{-n\delta}}$$

and

$$d = y_{st}\frac{1 + e^{-n_2\delta}}{1 - e^{-n\delta}}$$

Of particular interest is the amplitude range which will be denoted as $2\,y_{osc} = b' + y_{st} + d'$. Since $b' = be^{-\delta/2}$ and $d' = de^{-\delta/2}$, we have

$$y_{osc} = \frac{y_{st}}{2} + \frac{y_{st}\,(2 + e^{-n_1\delta} + e^{-n_2\delta})e^{-\delta/2}}{2(1 - e^{-n\delta})}$$

$$y_{osc} = y_{st}\left[\frac{1}{2} + \frac{2 + e^{-n_1\delta} + e^{-n_2\delta}}{2(1 - e^{-n\delta})e^{\delta/2}}\right] \quad \ldots\ldots\ldots\ldots [1]$$

The logarithmic decrement δ is a very small quantity, and even the product $n\delta$ is usually less than unity. Under those circumstances an approximation of Equation [1] by means of series expansion is indicated, especially since it allows a better insight into some of the factors involved.

With

$$e^x = 1 + x + \frac{x^2}{2} + \frac{x^3}{6} \ldots\ldots$$

it follows that

$$y_{osc} = y_{st}\left[\frac{1}{2} + \frac{2 + \left(1 - n_1\delta + \frac{n_1^2\delta^2}{2} - \frac{n_1^3\delta^3}{6} \ldots\ldots\right) + \left(1 - n_2\delta + \frac{n_2\delta^2}{2} - \frac{n_2^3\delta^3}{6} \ldots\ldots\right)}{2\left(n\delta - \frac{n^2\delta^2}{2} + \frac{n^3\delta^3}{6} \ldots\ldots\right)\left(1 + \frac{\delta}{2} + \frac{\delta^2}{8} \ldots\ldots\right)}\right]$$

Since $n_1 + n_2 = n$, this can be written

$$y_{osc} = y_{st}\left[\frac{1}{2} + \frac{4 - n\delta + \frac{n^2\delta^2}{2} - n_1n_2\delta^2 - \frac{n_1^3\delta^3}{6} - \frac{n_2^3\delta^3}{6} \ldots\ldots}{n\delta\left(2 - \frac{n\delta}{2} + \frac{n^2\delta^2}{6} \ldots\right)\left(1 + \frac{\delta}{2} + \frac{\delta^2}{8} \ldots\right)}\right]$$

Neglecting higher orders, this reduces to

$$y_{osc} = y_{st}\left[\frac{1}{2} + \frac{2 + \frac{n\delta}{2}}{n\delta\left(1 + \frac{\delta}{2}\right)}\right]$$

Neglecting further $\delta/2$ compared with 1, the following simple formula is derived

$$y_{osc} = y_{st}\left(1 + \frac{2}{n\delta}\right) \quad \ldots\ldots\ldots\ldots\ldots [2]$$

While Equation [2] is approximate, it shows the essentials clearly. As would be expected, with zero damping, amplitude and stress become infinite.

With a given steam force P_s on a given blade, the length of the arc of admission has a negligible effect on the blade stress. It is represented by n_2, which does not enter into the approximate Equation [2].

In a typical case (n = 30 cycles per revolution and logarithmic decrement δ = 0.01) Equation [2] would give

$$y_{osc} = y_{st}\left(1 + \frac{2}{0.3}\right) = 7.67\,y_{st}$$

The exact Equation [1] gives, for $n_1 = 14^1/_2$ cycles, $n_2 = 15^1/_2$ cycles

$$y_{osc} = y_{st}\left[\frac{1}{2} + \frac{2 + 0.865 + 0.856}{2(1 - 0.7408)(1.005)}\right] = 7.65\,y_{st}$$

and for $n_1 = 2^1/_2$ cycles, $n_2 = 27^1/_2$ cycles

$$y_{osc} = y_{st}\left[\frac{1}{2} + \frac{2 + 0.975 + 0.769}{2(1 - 0.7408)\,1.005}\right] = 7.70\,y_{st}$$

It is seen that oscillating stresses equal to many times the static steam stresses can be set up. It is this magnification of stress which endangers the life of impulse blades.

For the type of loading assumed, these stresses are practically inversely proportional to the damping. This emphasizes the great importance of damping as a quality with which blade constructions must be endowed.

On low-pressure blades, the remedy against large vibratory stresses consists of tuning the blade carefully so that it does not operate at resonance. This, of course, is possible only in machines with constant speed. On impulse blades it is not possible to tune the blades so they operate out of resonance, i.e., the resonant frequencies are too close together. If there is resonance

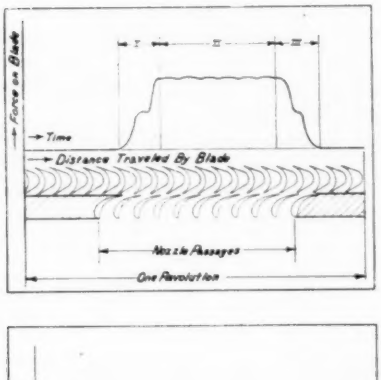

FIG. 2 GENERAL DIAGRAM OF INTERMITTENT STEAM LOAD

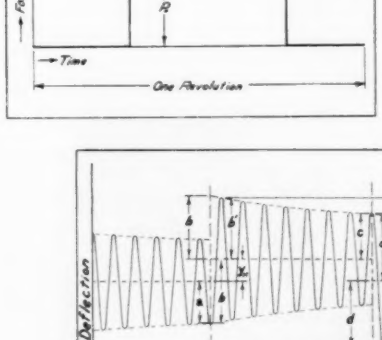

FIG. 3 SIMPLIFIED BLADE-LOAD DIAGRAM

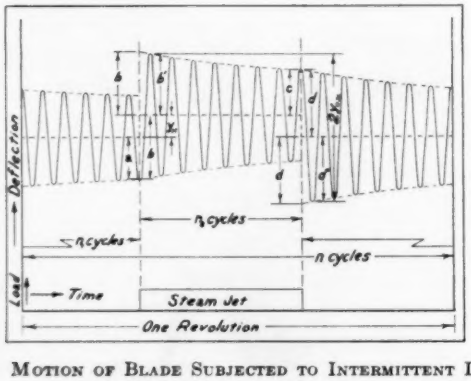

FIG. 4 MOTION OF BLADE SUBJECTED TO INTERMITTENT LOADING FORCES SHOWN IN FIG. 3

with 40 cycles per revolution at 3549 rpm, the next higher resonant speed will be 3640 rpm with 39 cycles per revolution. Thus, in this typical case the resonant speeds are $2^1/_2$ per cent apart. To make certain that the blades would operate between critical speeds, they would have to be tuned to within 1 per cent or less. This is practically impossible because of temperature variations (which influence the modulus of elasticity of the material and, hence, the frequency) and because of variations in the fit between rotor and blade.

Effect of Turbine Speed on Blade Stress

It is of particular interest to review the influence which the increase of turbine speed has had on impulse-blade stress. For

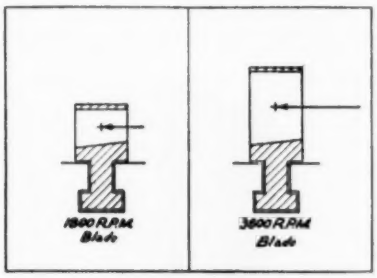

Fig. 5 Comparison Between Blades for 1800 Rpm and 3600 Rpm at Same Turbine Output

simplicity, let us compare two blades of the same cross section on turbines of the same kilowatt output, one machine operating at 1800 rpm, the other at 3600 rpm. Let us assume that the blade velocities, steam conditions, and arc of admission are identical on both turbines. The blades on the 3600-rpm machine will then be located on a mean diameter one half that of the 1800-turn machine.

To pass the same quantity of steam the blade port, or that part of the blade by which the steam is guided, must be twice as high for 3600 rpm as for 1800 rpm. Generally, the weakest section of the blades will be found where they are supported in the rotor. This section is a certain distance below the bottom of the blade port. In a typical case, shown in Fig. 5, the steady stresses in the weakest section would be in the ratio 8:3.

The blade frequencies vary approximately inversely with the square of the length. Therefore, the blade for 3600 rpm has roughly $^4/_9$ the frequency of the 1800-rpm blade, and n, the number of vibration cycles per revolution, is for the 3600-rpm turbine only $^2/_9$ of what it is for the 1800-rpm. This means that for very small damping values the oscillatory stresses in the 3600-rpm turbine are $\frac{9}{2} \times \frac{8}{3} = 12$ times as high as those of the 1800-rpm machine. With higher damping values this ratio decreases. This example illustrates the tremendous effect that increase in speed from 1800 to 3600 rpm has on impulse-blade stresses.

So far we have limited the discussion to one steam jet over the periphery. Often, for constructional reasons, it appears to be advantageous to have one series of nozzle passages in the base of the cylinder and another group in the cylinder cover. From Equation [2] it is clear, however, that if these passages would be located so each time the application and removal of the steam load would take place at the most unfavorable moment, the blade stress would be almost double that for the single series of nozzle passages. This means that this type of construction should be used only on blades with inherently low stress, or in such cases where the spacing of the nozzles is such that the additive effect of the "shocks" is precluded with certainty.

From low-pressure blades, operating in a slightly nonuniform steam flow (full admission), we are accustomed to having mechanical resonance when the blade frequency is a multiple of the running speed, e.g., when there is a whole number of free vibrations per revolution.

With the diagram assumed in Fig. 3 this is yet the case but, by taking diagrams of other shapes, it may easily be proved that the largest motions are often obtained when the number of vibrations per revolution is not an integer.

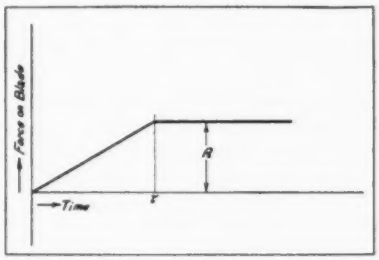

Fig. 6 Diagram of Load Applied Gradually

By applying the load more gradually, the oscillatory stresses can be reduced materially. A loading diagram such as shown in Fig. 6 is especially of interest.

If the load P_0 is applied gradually between $t = 0$ and $t = \tau$, the differential equation of the motion in this period is

$$m\frac{d^2y}{dt^2} + ky = P_0\frac{t}{\tau} \quad \ldots\ldots\ldots\ldots\ldots [3]$$

Here m and k are the equivalent mass and spring constant of the vibratory system. Damping forces during the loading period are neglected.

The solution of Equation [3] is, with $\omega = \sqrt{\frac{k}{m}}$

$$y = A\cos\omega t + B\sin\omega t + \frac{P_0 t}{k\tau} = A\cos\omega t + B\sin\omega t + y_{st}\frac{t}{\tau} \quad \ldots\ldots [3a]$$

At $t = \tau$ the amplitude is

$$y_\tau = A\cos\omega\tau + B\sin\omega\tau + y_{st} \quad \ldots\ldots\ldots\ldots [4]$$

and the velocity

$$v_\tau = -A\omega\sin\omega\tau + B\omega\cos\omega\tau + \frac{y_{st}}{\tau} \quad \ldots\ldots [5]$$

If the maximum amplitude reached after $t = \tau$ is a', we have the energy relation

$$\frac{1}{2}k(a'^2 - y_\tau^2) = P_0(a' - y_\tau) + \frac{1}{2}mv_\tau^2$$

Introducing Equations [4] and [5], this yields

$$(a' - y_{st})^2 = A^2 + B^2 + \frac{y_{st}}{(\omega\tau)^2} - \frac{2Ay_{st}}{\omega\tau}\sin\omega\tau + \frac{2By_{st}}{\omega\tau}\cos\omega\tau \quad \ldots [6]$$

If the amplitude before $t = 0$ was a, and if φ represents a phase angle between the time of maximum amplitude and the moment $t = 0$ when the load begins to be applied, we get from Equation [3a] the following initial boundary conditions at $t = 0$ (same displacement, same velocity as the free vibration existing for $t < 0$)

$$A = -a\cos\varphi$$

$$B = a \sin \varphi - \frac{y_{st}}{\omega\tau}$$

Inserting these values in Equation [6], we obtain with $\lambda = \omega\tau$

$$(a' - y_{st})^2 = a^2 + \frac{2y_{st}^2}{\lambda^2} - \frac{2y_{st}^2}{\lambda^2}\cos\lambda + \frac{2y_{st}}{\lambda}a\,(-\sin\varphi + \cos\varphi\sin\lambda + \sin\varphi\cos\lambda)$$

or

$$(a' - y_{st})^2 = a^2 + \frac{2y_{st}^2}{\lambda^2}(1 - \cos\lambda) + \frac{4y_{st}a}{\lambda}\left(\cos\frac{2\varphi+\lambda}{2}\sin\frac{\lambda}{2}\right)$$

So far, we have not specified at what phase of the existing vibration of amplitude a the load shall be applied. We will now choose the phase angle φ to give us the worst timing of the load, resulting in the largest increase in amplitude $(a' - a)$.

The maximum positive value of $\cos\frac{2\varphi+\lambda}{2}\sin\frac{\lambda}{2}$ is $\pm\sin\frac{\lambda}{2}$ for $\cos\frac{2\varphi+\lambda}{2} = \pm 1$, depending upon whether $\sin\frac{\lambda}{2}$ is positive or negative.

Thus we get for the largest increase in amplitude

$$(a' - y_{st})^2 = a^2 + \frac{4y_{st}^2}{\lambda^2}\sin^2\frac{\lambda}{2} \pm \frac{4y_{st}}{\lambda}a\sin\frac{\lambda}{2}$$

or

$$(a' - a) - y_{st} = \pm\frac{2y_{st}}{\lambda}\sin\frac{\lambda}{2} \quad \ldots\ldots\ldots\ldots [7]$$

Equation [7] gives a relation between the maximum increase in amplitude and the time in which the load is gradually increased from 0 to its final value. Since the natural period T of the free undamped vibration is $2\pi/\omega$, λ can be written as $\frac{2\pi\tau}{T}$, and Equation [7] becomes

$$\eta = \frac{(a' - a) - y_{st}}{y_{st}} = \frac{T}{\pi\tau}\sin\frac{\pi\tau}{T} \quad \ldots\ldots\ldots\ldots [8]$$

The factor η, which is a measure of the severity of the load changes, is thus seen to depend upon the length of loading period compared with the natural period of the blades.

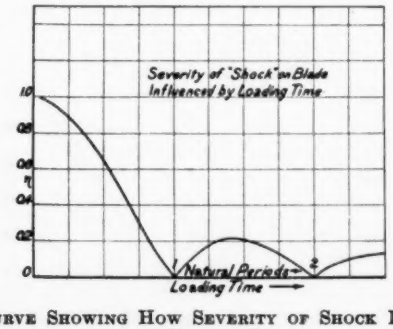

FIG. 7 CURVE SHOWING HOW SEVERITY OF SHOCK DEPENDS ON LOADING TIME OF BLADES

A plot of η against T/τ is given in Fig. 7.

It is at once clear that, where the loading is completed in one, two, or more natural periods ($\sin\pi\tau/T = 0$) the factor η will become zero. This means that, in this case, no matter what the phase relation is between the instant the load begins to be applied and the existing vibration, the only effect of the load will be that the oscillatory motion is shifted an amount equal to the static deflection.

If the load is both applied and removed in this fashion, the stress varies simply between zero and the steady steam stress, just as if the steam load were applied at an infinitely slow rate. This corresponds to the ideal minimum duty of the blade required to carry a certain steam force with partial admission.

The foregoing analysis indicates one way of reducing blade stresses under partial admission by means of a more gradual application of the steam load.

While blade frequencies can be precalculated with a reasonable degree of accuracy, the two other factors involved, namely, the exact nature of the steam shock and the damping of the blades, can be reliably determined by experiment only.

DETERMINING THE DAMPING OF BLADE STEELS

To determine the damping of blade steels at the temperature and the frequency pertaining to actual operation, we resorted to testing specimens in the shape of large tuning forks. This form of specimen had two obvious advantages. The vibratory forces in the fork are so nearly balanced that the exact way in which the fork is held is immaterial so far as the vibration of the prongs is concerned. The stress distribution in the prong is similar to that of the blade, so that any doubtful transfer from one state of stress to another is avoided.

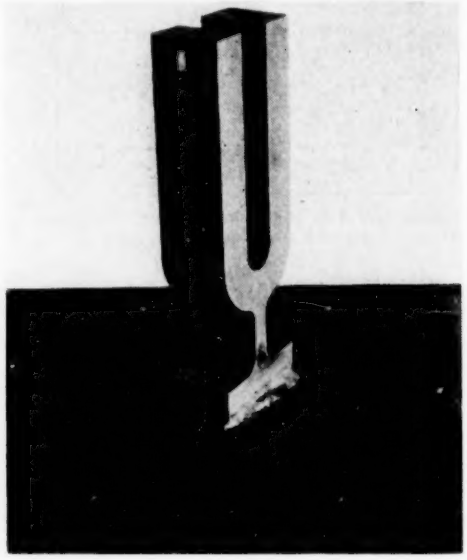

FIG. 8 TUNING-FORK SETUP FOR MEASURING DAMPING CAPACITY

Fig. 8 shows one of the test tuning forks mounted on a heavy block. The vibration of the tuning fork is recorded optically by means of a mirror clamped to the tip of one of the prongs, so that no energy is dissipated in the recording system. Suspicions about air friction around the forks were removed by making some of the tests in vacuum.

Even in recent literature the damping values of steels are innocently given as constant. We now know that the decrement depends vitally on stress and also on frequency and, as would be expected, on temperature.

For example, Dr. S. Siegel, physicist at the Westinghouse Research Laboratories, testing small bars in longitudinal vibration at 35,000 cycles per sec with stresses of ± 30 psi, finds damping values only $^1/_{30}$ of those found on large tuning forks (bending) at 750 cycles per sec and at a maximum stress of 20,000 psi.

Some typical damping curves obtained on various blade materials at room temperature are shown in Fig. 9 in the working-stress range. It is seen that there is considerable difference

between these materials. The 12 per cent Cr steel has, in the working-stress range, about 10 times as much damping as the Cr-Ni steels.

Some other characteristics, damping as function of temperature and frequency, are shown in Figs. 10 and 11. A great deal more fundamental work seems to be necessary before a clear understanding of what constitutes damping can be reached.

Besides internal damping in the materials, there is a certain amount of damping caused by microscopic rubbing and impacting along the fits between rotor and blades and in the shroud connections. However, unless there has been established a very definite lower limit of this external damping, it appears to be good practice to take for design purposes only the available internal damping of the blade materials. Our experience with *T*-roots indicates that the damping contributed by small motions between rotor and blade is negligible in this case.

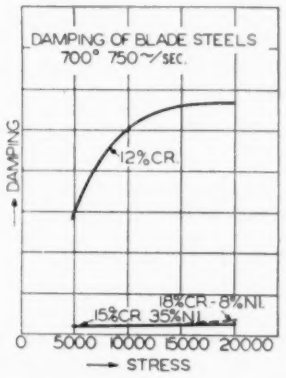

FIG. 9 DAMPING OF BLADE MATERIALS AS A FUNCTION OF STRESS

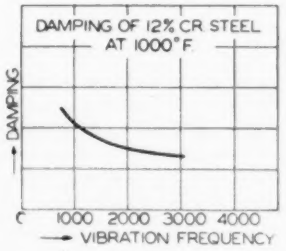

FIG. 10 DAMPING OF BLADE MATERIALS AS A FUNCTION OF FREQUENCY

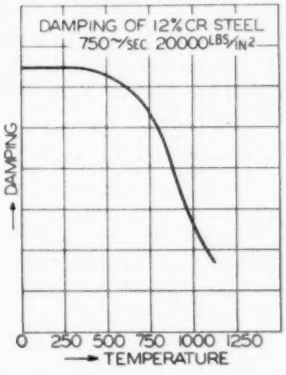

FIG. 11 DAMPING OF BLADE MATERIALS AS A FUNCTION OF TEMPERATURE

NATURE OF STEAM FORCES ACTING ON BLADE

To determine the nature of the steam forces acting on the blades while in operation, an optical system is used. This system and the experimental turbines on which it was applied have been described[2] recently and will only be mentioned here.

[2] "Superposed Turbine Blade Research," by F. T. Hague, *Mechanical Engineering*, vol. 61, April, 1940, pp. 275–277.

Light from an external source, Fig. 12, is deflected by a stationary slanted mirror into the hollow shaft. After passing a quartz window, which is needed to prevent the steam from leaking out, the light beam strikes a whirling mirror which projects it through a hole in the rotor and the blade toward a small mirror plug held at the tip of the blade. This small mirror reflects the light back by way of the inclined rotating mirror out through the shaft to the screen or film. The light beam is focused on the screen eccentrically so that, when the spindle rotates without blade vibration, the light spot describes a circle. When the blades vibrate, the light beam is deflected away from this circular path and waves appear. The stresses in the blades are deduced directly from the magnitude of the waves.

Turbine-blade vibrations occur both in the circumferential direction (in the plane of rotation) and in the lateral direction. Since we wish to record both motions separately, we need some sort of filtering device. For this purpose we have in the optical system a cylindrical lens of short focal length. The light beams striking this lens are so nearly parallel that the lens focuses them all practically on one focal line in the plane of the screen. While motion of the light beam along the longitudinal axis of the lens is transmitted undistorted along the focal line, motion in the perpendicular direction is cut out almost entirely. As shown in Fig. 12, the setup will record lateral blade motions; to record circumferential motion the cylindrical-lens assembly should be rotated 90 deg.

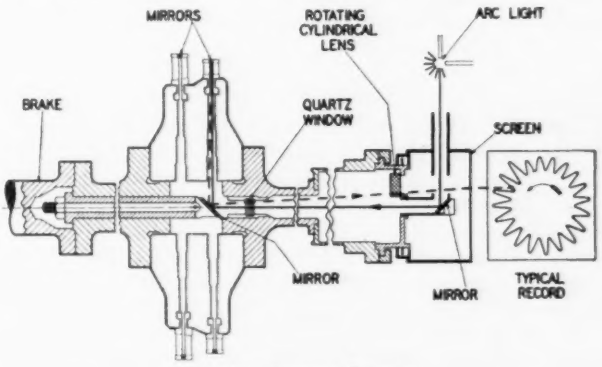

FIG. 12 OPTICAL SYSTEM

To date more than 30,000 individual records of blade vibration have been obtained for a wide range of operating conditions. After this test work is completed, it will be the subject of another paper.

Once the fundamentals are clearly understood, the nature of the various means of reducing blade stress under partial admission is clearly indicated:

1 The designer should, in general, strive to obtain short blades and light steam loads on the blades as long as this does not result in poor turbine efficiency. Shorter blades also mean higher natural frequencies so that the vibratory motion can die out more rapidly between successive loading periods.

2 Arranging the nozzles in a continuous sequence so that there is never more than one loading and unloading of the blades during one revolution is advantageous.

3 By applying effectively the steam load gradually at a certain rate, the stresses can be reduced materially.

4 More damping, internal or external, decreases blade stress.

ACKNOWLEDGMENT

Convergence of Hardy Cross's Balancing Process

By RUFUS OLDENBURGER,[1] CHICAGO, ILL.

It can be shown easily that the Cross method of structural analysis may be applied to a given structure in such a manner that the process does not converge. In this paper the author gives necessary and sufficient conditions for the convergence of the Cross method, and exhibits a convergent process of balancing any given structure. In particular he shows that a balancing process can be described by real linear transformation, that is, by a matrix of real numbers, and that the process converges in the sense of this paper if and only if the infinite power of this matrix exists and is zero. The study is restricted to the case of a continuous beam.

1—Introduction

HARDY CROSS has introduced a process[2] of structural analysis by balancing moments against each other in successive steps, this process being part of an infinite procedure. It has been used by many engineers, as for example by Grinter.[3] Southwell[4] has given an equivalent method, the convergence of which was considered in a paper by Temple.[5] Using energy considerations, Temple gave two convergent methods of applying the Southwell process to a given structure.

One can easily show that the Cross method may be applied to a given structure in such a manner that the process does not converge.[6] In the present paper the author gives necessary and sufficient conditions for the convergence of the Cross method, and exhibits a convergent process of balancing any given structure. In particular, he shows that a balancing process P can be described by real linear transformation, that is, by a matrix composed of real numbers, and that the process P converges in the sense of this paper if and only if the infinite power of this matrix exists and is zero. The existence and vanishing of the infinite power of a real matrix has been treated elsewhere.[7] For a discussion of matrices and their applications, the reader is referred to a book by Frazer, Duncan, and Collar.[8]

The study in this paper is restricted to a continuous beam. The argument for a network of beams is similar to that given here.

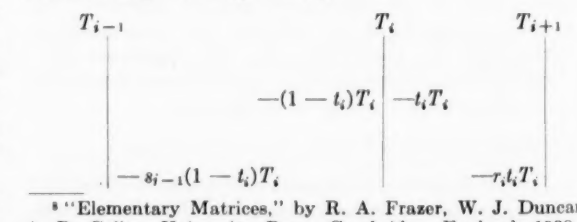
2—Description of the Hardy Cross Process for a Continuous Beam

We suppose that we have a beam B supported at both ends, these ends being free or fixed. Let S be an intermediate support. We associate with the left and right sides of S real numbers, so that with S is associated a pair of real numbers (a, b). Although the meaning of these numbers is immaterial to the following mathematical deductions it may be mentioned here that they are certain bending moments which would exist if the system were changed to a system of independent beams each fixed at all of the given supports. In the present paper we shall follow a convention used by Grinter[3] about positive and negative signs attributed to moments so that the final equilibrium is reached if the sum of the moments at each support is zero.

When the support S is balanced by the Hardy Cross method, the pair of numbers (a, b) is replaced in a certain way by a pair of real numbers $(\alpha, -\alpha)$ whose sum vanishes. With an end support E of B we associated one real number a, and when E is balanced we replace a by 0. A fixed end E is not balanced. The purpose of the Hardy Cross balancing process is through balancing to replace the numbers at the supports of B by a set of numbers where the sum of the numbers at each support is arbitrarily small.

For further descriptive details the reader is recommended to read the papers[2,3,4,5,7] referred to previously. A precise mathematical formulation of the Hardy Cross process will follow immediately.

3—The Balancing Process in Terms of Matrices



At any stage in the balancing process, the numbers at the i-th support add up to a number which we shall denote by T_i. If we now balance this support the theory of beams on unyielding supports prescribes that only the numbers at the $(i-1)$-st, i-th, and $(i+1)$-st supports are affected. Explicitly, we have the pattern

T_{i-1}	T_i	T_{i+1}

and after balancing we have the pattern

$T_{i-1} - s_{i-1}(1-t_i)T_i$	0	$T_{i+1} - r_i t_i T_i$

obtained by performing the steps

[8] "Elementary Matrices," by R. A. Frazer, W. J. Duncan, and A. R. Collar, University Press, Cambridge, England, 1938. The authors give an extensive treatment of matrix powers and discuss in special cases how high powers of a real matrix a are related to the latent (characteristic) roots of a, and how the existence of the infinite power of a depends on the latent roots.

The r's, s's, and t's are given constants which depend on the elastic properties of the beams right and left of the support considered.

Let there be n supports so that i ranges over 1, 2, ..., n. If the first support is a free end, $t_1 = 1$; similarly, if the n-th end is a free end, $t_n = 0$. If one or both of the end supports is a fixed end, we balance only the remaining supports.

The sets of constants $T_1, \ldots, T_n$ can be arranged in a column, called a "column vector," namely

$$v = \begin{Vmatrix} T_1 \\ T_2 \\ \cdot \\ \cdot \\ \cdot \\ T_n \end{Vmatrix} \quad \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

The corresponding vector after balancing the i-th support is, in the sense of matrix multiplication,[9] the product $a_i v$, where

$$a_i = \begin{Vmatrix} 1 & 0 & 0 & \cdot & \cdot & \cdot & 0 \\ 0 & 1 & 0 & \cdot & \cdot & \cdot & 0 \\ & \cdot & & & & & \\ & & \cdot & & & & \\ & & & \cdot & & & \\ 0 & \ldots & 01 & 0 & 0 & 0 \ldots & 0 \\ 0 & \ldots & 0 & 1 & [-s_{i-1}(1-t_i)] & 0\ 0 \ldots & 0 \\ 0 & \ldots & 0 & 0 & 0 & 0\ 0 \ldots & 0 \\ 0 & \ldots & 0 & -r_i t_i & 1 & 0 \ldots & 0 \\ 0 & \ldots & 0 & 0 & 0 & 1\ 0 \ldots & 0 \\ & & & & & & \cdot \\ & & & & & & \cdot \\ & & & & & & \cdot \\ 0 & & & \cdot & \cdot & \cdot & 01 \end{Vmatrix} \quad \ldots [2]$$

which can be written as

$$a_i = \begin{Vmatrix} I_1 & 0 & 0 \\ 0 & B_i & 0 \\ 0 & 0 & I_2 \end{Vmatrix} \quad \ldots\ldots\ldots\ldots\ldots [3]$$

where I_1, I_2 are "minors" with 1's on the diagonal and zeros elsewhere, and B_i is the minor

$$\begin{Vmatrix} 1 & -s_{i-1}(1-t_i) & 0 \\ 0 & 0 & \\ 0 & -r_i t_i & 1 \end{Vmatrix}$$

If we now balance the j-th column the numbers at the supports form a column vector given by $a_j a_i v$. Thus after a sequence of balancing the numbers at the supports are given by a product

$$a_\alpha a_\beta \ \ldots\ a_\lambda a_\xi a_\delta v \ldots\ldots\ldots\ldots\ldots\ldots [4]$$

which can be written more simply as av, where a is the matrix $a_\alpha a_\beta \ldots a_\delta$.

Since we do not balance fixed ends, we may restrict v to be a vector composed of the numbers at the remaining supports.

We term the element in the i-th row and j-th column of a matrix the (i, j)-th element of this matrix.

Let $c_1, c_2, \ldots$ be an infinite sequence of n by m matrices.[10] We say that this sequence has a limit c if for each pair of values i, j the (i, j)-th elements of $c_1, c_2, \ldots$ have the (i, j)-th element of c as a limit in the usual sense. We write this as

$$\lim_{\alpha \to \infty} c_i = c \ldots\ldots\ldots\ldots\ldots\ldots [5]$$

The balancing process, if performed indefinitely, converges in the sense of this paper if and only if the successive products v, $a_\delta v$, $a_\xi a_\delta v$, $a_\lambda a_\xi a_\delta v$, ... of the type [4] approach the vector

$$0 = \begin{Vmatrix} 0 \\ \cdot \\ \cdot \\ \cdot \\ 0 \end{Vmatrix} \quad \ldots\ldots\ldots\ldots\ldots\ldots [6]$$

as a limit.

Example. We consider a case of four supports with the right end fixed. We take the constants as indicated in the pattern

$$\begin{array}{cccc} T_1 = 5 & T_2 = 2 & T_3 = 3 & T_4 = 1 \\ \Big| & \Big| & \Big| & \Big| \\ r_1 = 1/2 & r_2 = 1/3 & r_3 = 1/6 & \\ s_1 = 1/4 & s_2 = 1/5 & s_3 = 1/2 & \\ \Big| & \Big| & \Big| & \\ t_1 = 1 & t_2 = 1/3 & t_3 = 1/2 & \end{array}$$

We take

$$v = \begin{Vmatrix} T_1 \\ T_2 \\ T_3 \end{Vmatrix} = \begin{Vmatrix} 5 \\ 2 \\ 3 \end{Vmatrix} \quad \ldots\ldots\ldots\ldots\ldots [7]$$

The matrices a_1, a_2, a_3 which correspond to balancing the first, second, and third supports are respectively

$$\begin{Vmatrix} 0 & 0 & 0 \\ -r_1 t_1 & 1 & 0 \\ 0 & 0 & 1 \end{Vmatrix} = \begin{Vmatrix} 0 & 0 & 0 \\ -1/2 & 1 & 0 \\ 0 & 0 & 1 \end{Vmatrix} \quad \ldots\ldots\ldots [8]$$

$$\begin{Vmatrix} 1 & -s_1(1-t_2) & 0 \\ 0 & 0 & 0 \\ 0 & -r_2 t_2 & 1 \end{Vmatrix} = \begin{Vmatrix} 1 & -1/8 & 0 \\ 0 & 0 & 0 \\ 0 & -1/6 & 1 \end{Vmatrix} \quad \ldots\ldots\ldots [9]$$

$$\begin{Vmatrix} 1 & 0 & 0 \\ 0 & 1 & -s_2(1-t_3) \\ 0 & 0 & 0 \end{Vmatrix} = \begin{Vmatrix} 1 & 0 & 0 \\ 0 & 1 & -1/10 \\ 0 & 0 & 0 \end{Vmatrix} \quad \ldots\ldots [10]$$

We are disregarding the fourth support since it is a fixed end.

If we balance the second, third, and first supports in this order we obtain $v_1 = a_1 a_3 a_2 v$ where specifically

$$v_1 = \begin{Vmatrix} 0 & 0 & 0 \\ -1/2 & 1 & 0 \\ 0 & 0 & 1 \end{Vmatrix} \cdot \begin{Vmatrix} 1 & 0 & 0 \\ 0 & 1 & -1/10 \\ 0 & 0 & 0 \end{Vmatrix} \cdot \begin{Vmatrix} 1 & -1/8 & 0 \\ 0 & 0 & 0 \\ 0 & -1/6 & 1 \end{Vmatrix} \cdot \begin{Vmatrix} 5 \\ 2 \\ 3 \end{Vmatrix} \quad \ldots [11]$$

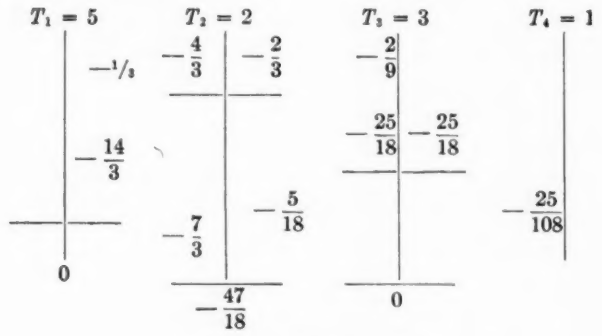
which upon multiplying the matrices successively yields

$$v_1 = \begin{Vmatrix} 0 & 0 & 0 \\ -1/2 & 1 & 0 \\ 0 & 0 & 1 \end{Vmatrix} \cdot \begin{Vmatrix} 1 & 0 & 0 \\ 0 & 1 & -1/10 \\ 0 & 0 & 0 \end{Vmatrix} \cdot \begin{Vmatrix} \frac{14}{3} \\ 0 \\ \frac{25}{9} \end{Vmatrix} =$$

$$\begin{Vmatrix} 0 & 0 & 0 \\ -1/2 & 1 & 0 \\ 0 & 0 & 1 \end{Vmatrix} \cdot \begin{Vmatrix} \frac{14}{3} \\ -5/18 \\ 0 \end{Vmatrix} = \begin{Vmatrix} 0 \\ -47/18 \\ 0 \end{Vmatrix} \quad \ldots\ldots [12]$$

Now if we write $a = a_1 a_3 a_2$, then $v_1 = av$ and

$$a = \begin{Vmatrix} 0 & 0 & 0 \\ -1/2 & \frac{17}{180} & -\frac{1}{10} \\ 0 & 0 & 0 \end{Vmatrix} \quad \ldots\ldots\ldots [13]$$



Thus the numbers at the supports are now

0	$-\frac{47}{18}$	0	*

[9] For the matrix theory used here the reader is referred to "Theory of Matrices," by C. C. MacDuffee, *Ergebnisse der Mathematik*, Julius Springer & Sons, Berlin.

[10] An n by m matrix is by definition a matrix with n rows and m columns.

Direct balancing yields the same result as is clear from the scheme which follows

4—Repeated Balancing

It is obvious that restrictions must be put on the balancing process to insure its convergence in the sense of this paper. Since a balancing performed by an individual can involve only a finite set F of steps, it is no restriction to assume that if the balancing were continued indefinitely, we would do this by repeating the set F of steps over and over. Let v be the original vector, whose elements are the numbers $T_1, T_2, \ldots, T_n$ at the supports to be balanced. The vector v_1 obtained by the steps F from v, is $v_1 = av$, where a is a product of matrices of the type a_i defined in Section 3. If we perform the steps F again we obtain from v_1 a vector v_2 related to v_1 by the formula

$$v_2 = av_1 \quad [14]$$

whence

$$v_2 = a(av) = a^2v \quad [15]$$

Thus after performing the set F of steps m times we arrive at a vector v_m related to v by the formula

$$v_m = a^m v \quad [16]$$

By Section 3 the balancing process converges if and only if

$$\lim_{m \to \infty} v_m = 0 \quad [17]$$

For arbitrary v, $\lim v_m = 0$ as $m \to \infty$ if and only if $\lim a^m = 0$ as $m \to \infty$. We shall use the notation a^∞ for

$$\lim_{m \to \infty} a^m$$

It has been proved[7] that $a^\infty = 0$ if and only if the characteristic roots of a are in absolute value less than 1. We term a the matrix of the balancing process. We have therefore arrived at the following result: (See next column.)

Theorem: Balancings with matrix a converge if and only if the characteristic roots of a are less than 1 in absolute value.

Example. We consider the matrix a in the example of Section 3. Subtracting a variable λ from the diagonal elements of a we obtain the matrix $a - \lambda I$ given by

$$\begin{Vmatrix} -\lambda & 0 & 0 \\ -\frac{1}{2} & \frac{17}{180} - \lambda & -\frac{1}{10} \\ 0 & 0 & -\lambda \end{Vmatrix}$$

Here I denotes the identity matrix with 3 rows and 3 columns; I is a matrix with 1's on the diagonal and zeros elsewhere. The characteristic determinant of a is the determinant $|a - \lambda I|$ given by

$$\begin{vmatrix} -\lambda & 0 & 0 \\ -\frac{1}{2} & \frac{17}{180} - \lambda & -\frac{1}{10} \\ 0 & 0 & -\lambda \end{vmatrix}$$

The characteristic equation of a is the equation $|a - \lambda I| = 0$, whose roots are 0, $\frac{17}{180}$, and 0. Since these roots are in absolute value less than 1, the balancing process with matrix a converges if repeated indefinitely.

5—A Converging Process

In Section 4 we have given an answer to the question: When does the balancing process converge? In the present section we shall give a converging balancing process that may be applied to any given set of supports.

Let there be n given supports. It is no restriction to suppose that $0 \leqq t_i \leqq 1$ and $0 \leqq r_i < 1, 0 \leqq s_i < 1$. We can obviously balance the 1st, 3rd, 5th, ... supports so that the vector of the numbers at these supports is

$$v = \begin{Vmatrix} 0 \\ T_2 \\ 0 \\ T_4 \\ 0 \\ \vdots \\ T_n \end{Vmatrix} \quad [18]$$

The last element T_n is zero if n is odd. We now balance the even-numbered supports, and then the odd-numbered supports. In place of the vector v we now have a vector $v' = av$, where (See Equation 19 below.)

$$a = \begin{Vmatrix} 0 & 0 & 0 & 0 & 0 & 0 \ldots 0 \\ 0 & \left[\begin{matrix} r_1 t_1 s_1 (1 - t_2) \\ + r_2 t_2 s_2 (1 - t_3) \end{matrix}\right] & 0 & s_2 s_3 (1 - t_3)(1 - t_4) & 0 & 0 \ldots 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \ldots 0 \\ 0 & r_2 r_3 t_2 t_3 & 0 & \left[\begin{matrix} r_3 t_3 s_3 (1 - t_4) \\ + r_4 t_4 s_4 (1 - t_5) \end{matrix}\right] & 0 & s_4 s_5 (1 - t_5)(1 - t_6) \quad 0 \quad 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \ldots 0 \\ 0 & 0 & 0 & r_4 r_5 t_4 t_5 & 0 & \left[\begin{matrix} r_5 t_5 s_5 (1 - t_6) \\ + r_6 t_6 s_6 (1 - t_7) \end{matrix}\right] \quad 0 \quad 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \ldots 0 \quad 0 \quad 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \qquad \cdot \quad \cdot \end{Vmatrix} \quad [19]$$

If a is of order n, n even, the last bracket quantity in a is simply $[r_{n-1}t_{n-1}s_{n-1}(1-t_n)]$. As noted in Section 4, if the first end is free, $t_1 = 1$, if the last is free, $t_n = 0$. Except for a power of λ, the characteristic determinant $|a - \lambda I|$ (I here is again the identity matrix with 1's on the diagonal and zeros elsewhere) of a is the characteristic determinant of the matrix a', where

$$a' = \begin{Vmatrix} \begin{bmatrix} r_1s_1t_1(1-t_2) \\ + r_2s_2t_2(1-t_3) \end{bmatrix} & s_2s_3(1-t_3)(1-t_4) & 0 & 0 \cdot \cdot \cdot \cdot 0 \\ r_3r_3t_2t_3 & \begin{bmatrix} r_3s_3t_3(1-t_4) \\ + r_4s_4t_4(1-t_5) \end{bmatrix} & s_4s_5(1-t_5)(1-t_6) & 0 \cdot \cdot \cdot \cdot 0 \\ 0 & r_4r_5t_4t_5 & \begin{bmatrix} r_5s_5t_5(1-t_6) \\ + r_6s_6t_6(1-t_7) \end{bmatrix} & s_6s_7(1-t_7)(1-t_8) \; 0 \; 0 \\ 0 & 0 & r_6r_7t_6t_7 & \begin{bmatrix} r_7s_7t_7(1-t_8) \\ + r_8s_8t_8(1-t_9) \end{bmatrix} \; \cdot \; \cdot \\ \cdot & \cdot & \cdot & \cdot \cdot \cdot \cdot \cdot \cdot \end{Vmatrix} \quad \cdots\cdots\cdots [20]$$

The characteristic roots of a are 0 and the roots of $|a' - \lambda I| = 0$. We note that a' has the shape

$$a = \begin{Vmatrix} * & * & 0 & 0 & \cdot & \cdot & \cdot & 0 \\ * & * & * & 0 & \cdot & \cdot & \cdot & 0 \\ 0 & * & * & 0 & \cdot & \cdot & \cdot & 0 \\ \cdot & \cdot & & \cdot & & & & \vdots \\ \cdot & & & & \cdot & & \cdot & 0 \\ \cdot & & \cdot & & & & * & * \\ 0 & \cdot & \cdot & 0 & & & * & * \end{Vmatrix} \quad \cdots\cdots\cdots [21]$$

where the asterisks stand for numbers that may be different from zero.

We observe that the elements of a' are positive or zero. It has been proved[7] that an increase in some of these numbers will either leave the maximum absolute value of the characteristic roots of a' unchanged, or it will increase this value. Since for each i we have $r_i < 1$ and $s_i < 1$, there is a positive number r less than 1 such that the r_i and s_i are less than r for each i. Replace each r_i and each s_i in a' by r to obtain a matrix

$$a'' = \begin{Vmatrix} r^2[t_1(1-t_2) + t_2(1-t_3)] & r^2(1-t_3)(1-t_4) & 0 & 0 \; 0 \\ r^2t_2t_3 & r^2[t_3(1-t_4) + t_4(1-t_5)] & r^2(1-t_5)(1-t_6) & 0 \; 0 \\ 0 & r^2t_4t_5 & r^2[t_5(1-t_6) + t_6(1-t_7)] & \cdot \cdot \cdot \\ \cdot & \cdot & \cdot & \cdot \cdot \cdot \end{Vmatrix} \quad \cdots\cdots [22]$$

We let p denote the order of a''. We let B denote the matrix obtained from a'' by replacing r^2 by 1 wherever r^2 occurs in a''. We can write

$$B = \begin{Vmatrix} [1-a_1-b_1] & a_2 & 0 & 0 & \cdot \cdot \cdot & 0 & 0 \\ b_1 & [1-a_2-b_2] & a_3 & 0 & \cdot \cdot \cdot & 0 & 0 \\ 0 & b_2 & [1-a_3-b_3] & a_4 & \cdot \cdot \cdot & 0 & 0 \\ 0 & 0 & b_3 & \cdot & & 0 & 0 \\ & & & \cdot & \cdot & a_{p-1} & 0 \\ & & & & \cdot & [1-a_{p-1}-b_{p-1}] & a_p \\ 0 & 0 & 0 \cdot \cdot \cdot \cdot 0 & & & b_{p-1} & [1-a_p-b_p] \end{Vmatrix} \quad \cdots\cdots [23]$$

where $a_i = (1 - t_{2i-1})(1 - t_{2i})$ for $i = 1, 2, \ldots, p$, and $b_i = t_{2i}t_{2i+1}$ for $i = 1, 2, \ldots, p$. Dividing each of the rows of $|a'' - \lambda I|$ by r^2 we find that the characteristic roots of a'' are the roots of $|B - (\lambda/r^2)I| = 0$. We write $\mu = \lambda/r^2$. If $\mu = 1$, then $\lambda = r^2 < 1$. Thus the maximum absolute value of the characteristic roots λ of a'' is less than 1 if the maximum absolute value of the characteristic roots μ of B is less than or equal to 1.

Frobenius[11] proved almost completely that a matrix a all of whose elements are positive or zero has a real positive characteristic root not less in absolute value than any other characteristic root of a. Since the t's are between 0 and 1, it is easy to see that the elements of B are between 0 and 1. To prove that the roots of $|B - \mu I| = 0$ are in absolute value not greater than 1, it is necessary to prove only that the maximum positive root μ of $|B - \mu I| = 0$ is not greater than 1. We thus wish to show that $|B - \mu I| = 0$ has no root $\mu = 1 + \epsilon$ where $\epsilon > 0$. Substituting $1 + \epsilon$ for μ in $|B - \mu I|$, and changing the sign of each row we obtain

$$D(\epsilon) = \begin{vmatrix} a_1 + b_1 + \epsilon & -a_2 & & & \bigcirc \\ -b_1 & a_2 + b_2 + \epsilon & \cdot & & \\ & \cdot & \cdot & & \\ & & & \cdot & -a_p \\ \bigcirc & & & -b_{p-1} & a_p + b_p + \epsilon \end{vmatrix} \quad \cdots\cdots [24]$$

[11] "Über Matrizen aus positiven Elementen," by S. B. Frobenius, Kgl. Preuss. Akad. d. Wiss., 1908, pp. 471–476.

Expanding $D(\epsilon)$ we get

$$D(\epsilon) = \epsilon^p + \alpha_1\epsilon^{p-1} + \alpha_2\epsilon^{p-2} + \alpha_{p-1}\epsilon + \alpha_p \quad [25]$$

By determinant theory the coefficient α_i of ϵ_i in Equation [25] is the sum of the principal determinant minors of $D(0)$ of order i. It is recalled that a principal determinant minor of $D(0)$ is a minor obtained by striking out the same rows as columns from $D(0)$.

We let m_i denote the leading principal determinant minor of $D(0)$ of order i. It is

$$m_i = \begin{vmatrix} (a_1 + b_1) & -a_2 & & \bigcirc \\ -b_1 & (a_2 + b_2) & & \\ & & & \\ \bigcirc & & -b_{i-1} & (a_i + b_i) \end{vmatrix} \quad [26]$$

We write $m_i[a_1, a_2, \ldots, a_i;\ b_1, b_2, \ldots, b_i]$ since m_i is a function of these constants. If we write $m_0 = 1$ we can prove that

$$m_i = a_1 m_{i-1}[a_2, \ldots, a_i;\ b_2, \ldots, b_i] + b_1 b_2 \ldots b_i \quad [27]$$

Here $m_{i-1}(a_2, \ldots, a_j;\ b_2, \ldots, b_i)$ is obtained from $m_{i-1}[a_1, a_2, \ldots, a_{i-1};\ b_1, \ldots, b_{i-1}]$ by replacing $a_1, \ldots, a_{i-1}$ by $a_2, \ldots, a_i$ respectively, and making a similar substitution on the b's. Since $a_1 \geqq 0$, $b_1 \geqq 0$, $\ldots$, $b_i \geqq 0$, it follows that if $m_{i-1} \geqq 0$, then $m_i \geqq 0$. Since $m_0 > 0$, it follows by mathematical induction that $m_i \geqq 0$ for each i. It can be easily proved that each principal minor is either of the same shape as m_i, or a product of such minors. Thus each principal determinant minor of $D(0)$ is $\geqq 0$, whence the coefficients $\alpha_1, \ldots, \alpha_p$ in Equation [25] are $\geqq 0$. Directly, or by Descartes rule of signs, one can see that there is no positive root of the equation $D(\epsilon) = 0$. Thus there is no root μ of $|B - \mu I| = 0$ greater than 1. It follows by retracing the foregoing argument that the characteristic roots of a are in absolute value less than 1 so that $a^\infty = 0$. Thus we have proved the following result:

Theorem: The process of balancing alternately odd and even supports converges.

Example. We take a case of four supports with free ends. We also take all the r's, s's and t's except t_1 and t_4 to be $\frac{1}{2}$. Evidently, $t_1 = 1$, $t_4 = 0$. Let the given T's be 1, —1, —2, and 2 respectively. The balancing of the odd-numbered supports yields

| 1 | —1 | —2 | 2 | ⟶ | 0 | —1 | 0 | 5/2 |

Thus

$$v = \begin{Vmatrix} 0 \\ -1 \\ 0 \\ 5/2 \end{Vmatrix} \quad [28]$$

If we balance the even-numbered supports, we obtain

| 0 | —1 | 0 | 5/2 | ⟶ | 1/4 | 0 | —1 | 0 |

If now we balance the odd-numbered supports, we get

| 1/4 | 0 | —1 | 0 | ⟶ | 0 | 1/8 | 0 | 1/4 |

The vector

$$v' = \begin{Vmatrix} 0 \\ 1/8 \\ 0 \\ 1/4 \end{Vmatrix} \quad [29]$$

is related to v by the equation $v' = av$ with matrix

$$a = \begin{Vmatrix} 0 & 0 & 0 & 0 \\ 0 & 3/16 & 0 & 1/8 \\ 0 & 0 & 0 & 0 \\ 0 & 1/16 & 0 & 1/8 \end{Vmatrix} \quad [30]$$

Now

$$|a - \lambda I| = \begin{vmatrix} -\lambda & 0 & 0 & 0 \\ 0 & 3/16 - \lambda & 0 & 1/8 \\ 0 & 0 & -\lambda & 0 \\ 0 & 1/16 & 0 & 1/8 - \lambda \end{vmatrix} = \lambda^4 - 5/16\lambda^3 + 1/64\lambda^2 \quad [31]$$

The characteristic roots of a are 0, 0, 1/16, 1/4 which are all in absolute value less than 1. Hence $a^\infty = 0$, and $\lim_{n \to \infty} a^n v = 0$.

Discussion

Boundary Friction in Bearings at Low Loads[1]

J. L. Fletcher.[2] It appears that the authors have confirmed what might be expected, that is, for boundary lubrication the rougher the surface the higher the coefficient of friction. And further, that for a given grinding process the softer the metal the rougher the surface.

A study of this paper has led to the following questions:

1 As finishing processes approach producing journal surfaces of zero roughness, or a roughness comparable with an oil-molecule thickness, would not the friction coefficient become practically equal for all types of metals?

2 If it were possible to get equal surfaces (rather than equal surfacing processes) would not the friction coefficient be equal for all metals, assuming no metal scoring?

3 This then leads to the question: Should not softer metals be finished by different processes from those for harder metals when boundary friction is to be encountered to an appreciable extent?

4 As the stainless steel showed considerable wear, it would be interesting to know whether or not the coefficient of friction for stainless was approaching that of nickel steel as the surface of the stainless approached the condition of the surface of the nickel steel. Because of this wear, can data taken at start of test be reliably compared with data taken at end of test?

The writer would welcome the authors' opinion on these questions. It is the writer's belief that as the metal surfaces approach being equal the coefficients of friction for boundary lubrication would become nearly equal. Further it is probable that it would pay to use a process for finishing the softer metals that would give a surface equal to that of a ground hard surface when there is much difference in material and hardening costs of the metals being considered.

J. R. Connelly.[3] The method of oil feed employed by the authors seems susceptible to uncontrolled variations in the test conditions. Some years ago the writer experimented with various rates of oil feed in connection with such work on "thin-film lubrication." From the results obtained it was concluded that if one desired results that would be reproducible by different experimenters some method of applying lubricant should be used that supplied the lubricant in unlimited quantities and that the viscosity should be varied by other means than starving the bearing.

To say that there was provided "enough oil for boundary lubrication but not enough to form a fluid film or to provide cooling" seems to the writer to be unsupported by the evidence. Any fluid or plastic (such as grease) third material inserted between journal and bearing is bound to take some energy from localized hot spots and distribute the energy through the third material. Is not this cooling? The amount of cooling then is affected by the amount of third material and the cooling will never be absent unless the third material is absent.

Whether a fluid film is formed depends on what is meant by a fluid film. The transition from "thick-film" to "thin-film" is not likely to be as definitely noticeable as the transition from thin-film to conditions of contact between the journal and bearing. The question remains then as to where in the transition zone between thick-film and thin-film, or even in the contact range, these tests were run.

Paul G. Exline.[4] It is well known that the roughness of bearing surfaces influences the behavior of a journal bearing to a considerable degree, particularly when operating in the boundary region. The recent development of instruments capable of measuring surface conditions enables investigators to add materially to the value of their papers, as the authors have done, by reporting the roughness data together with the performance data. As it seems evident that this commendable practice will increase in the future, the writer feels that an early discussion of the relative importance of different measurements is necessary. The authors report the maximum depths of the grinding scratches as measured on a line parallel to the axis of the journal. The writer in his own work uses an instrument which indicates the root-mean-square value of the heights of the irregularities but, due to the difficulty of circumferential measurements, the value is also taken on a line parallel to the axis. It is quite certain that under some conditions measurements made in the two directions would show widely varying results. A well-run-in journal quite often carries fairly deep grooves running completely around it which apparently do not interfere with its operation.

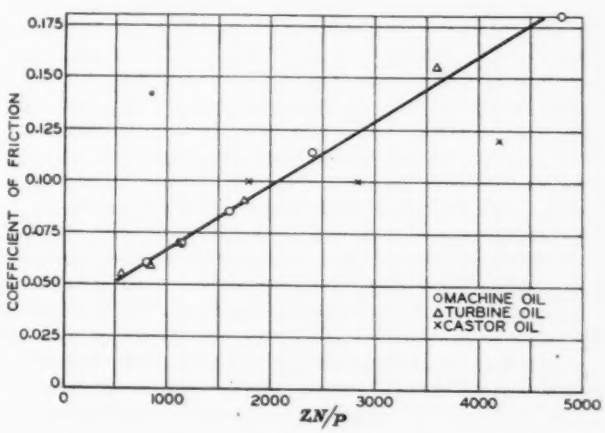


Fig. 1

The conditions under which a bearing operates in the boundary lubrication region are generally understood to be those which are in close proximity to the minimum point of the curve of coefficient of friction plotted against ZN/P. The method, used by the authors, in which the boundary region is reached by regulating the rate of oil flow to the bearing appears to offer a new technique for investigation but one which makes it exceedingly difficult to determine when the desired conditions are reached. Calculation

[1] By L. M. Tichvinsky and E. G. Fischer. Published in the September, 1939, issue of the Journal of Applied Mechanics, Trans. A.S.M.E., vol. 61, 1939, p. A-109.

based on the data presented in Figs. 10 and 16 of the paper indicate that the bearings were operating at very high values of ZN/P; and Fig. 1 of this discussion, plotted from such calculated data, gives no evidence that conditions were other than those of thick-film lubrication. Consequently, it would be desirable to know what criterion was used by the authors to indicate the correct rate of oil feed to the bearing to bring about the conditions of boundary lubrication.

F. P. Bowden.[5] The writer is in full agreement with the authors that the friction and wear between boundary lubricated metals was very dependent upon the nature of the metals. Experiments carried out in Cambridge[6] have shown that the sliding between metal surfaces might not be a continuous process. There is evidence that an intermittent clutching and breaking away of the surfaces occurs and that the friction, surface temperature, and area of contact all show violent fluctuations during sliding.

Even if the surfaces are ground flat and carefully polished, hills and valleys are still present on the surface, and where the metals are placed in contact they are supported on the summits of these irregularities so that the real area of contact is very small. This means that even with lightly loaded surfaces the local pressure is very great.[7] Experiment suggests that the pressure is great enough to cause the plastic flow of steel. If the sliding speed is high enough the heat liberated at the localized points of contact is sufficient to raise them to a very high temperature.

The results suggest that the friction is due to the formation and subsequent breaking of metallic junctions between the surfaces at these points of contact; although the junctions are small their dimensions are large compared with the dimensions of a molecule, so that when motion occurs and the junctions are broken, the metals are torn and distorted to a considerable degree beneath the surface.

Even with the best lubricant films the writer has always observed metallic contact and damage of the underlying metal. The picture reproduced by the authors of the adsorbed lubricant films sliding over one another might represent the ideal case, but the writer does not think it occurs in practice in kinetic friction. The intense local pressure causes a breakdown of the film so that local contact of the metals occurs. During sliding, this breakdown is aided by the local high temperature. The writer considers that friction cannot be regarded as a surface phenomenon. The strength of the junctions and the magnitude of the friction is influenced by the bulk properties of the metals. The effects of sliding extend to a great depth beneath the metal surface.

Experiments have suggested that the metallic junctions might be of three main types. The exact type which predominated is influenced by the *relative* physical properties, particularly by the relative melting point and relative hardness of the two metals. The worst type of junction which causes the highest friction and wear is that formed between similar metals and between metals of similar melting points. Because of this it is an advantage to choose metals of very different melting points, and the less important surface, e.g., the bearing, should have the lower melting point. Melting and flow of the surface will then occur before the local temperature can reach a sufficiently high value to cause a softening and damage of the journal. It is interesting that the authors found the lowest friction with babbitt metal.

[7] "The Area of Contact Between Stationary and Between Moving Surfaces," by F. P. Bowden and D. Tabor, Proceedings of the Royal Society of London, series A, vol. 169, Feb., 1939, p. 391.

The writer has also found, in agreement with the authors, that the exact value of the friction and wear is influenced to some extent by the method of preparation and surface finish of the metals. This effect might, however, be of much less importance than the bulk composition of the metals themselves. Some of the values of kinetic friction given in the paper were below 0.05. The writer has not observed values of boundary lubrication quite as low as this. Did the authors consider it possible that some fluid lubrication was occurring in their experiment?

There is also no doubt that the boundary kinetic friction and wear are dependent upon the shape and size of the lubricant molecule and on the method of attachment to the surface. In general, mineral oils are bad lubricants but recent experiments have shown that the presence on the surface of certain long-chain polar molecules is able to change the nature of the sliding so that intermittent stick-slip is prevented and the sliding proceeds continuously. At the same time the wear of the surfaces is greatly reduced. Substances which cause this change are in general good lubricants.

S. Kyropoulos.[8] The paper under discussion is a typical investigation from an engineering point of view. It differs from some other papers of these last years with similar objects by a more rigorous consideration of the factors involved, of which only the attention paid to surface conditions may be mentioned. For this reason the investigation is undoubtedly bound to meet with the appreciation it deserves in engineering circles. The rather well-defined conditions of experiment and the clarity with which conclusions are drawn must as well appeal to those studying the phenomena of boundary lubrication from a physicochemical viewpoint.

In view of the experience that the clear and well-supported conclusions of such investigations are apt to be expanded into general conclusions by later workers and in view of the introductory physicochemical remarks of the investigators which invite physicochemical comment, a few pertinent remarks might not be out of place.

In view of the introduction one would logically expect that the authors would attempt a correlation of data of static or kinetic friction of the oils used with the results obtained. Apart from the very important viscosity data of the oils no such properties are listed in the paper, an omission which, incidentally, the writer does not consider a serious deficiency. Nevertheless one has to draw conclusions from data on a by-effect (viscous lubrication) in order to estimate the effect appearing in the title of the paper. With regard to the very illustrative photomicrographs of the journal surfaces it would have appeared desirable to have pictures of the surfaces before testing and not only before running in. Furthermore, it should be emphasized that in all the experiments described in the paper we are dealing with mixed fluid and nonfluid (i.e., "boundary") lubrication. This follows from the investigations of Beare and Bowden[9] quoted by the authors, as well as Kyropoulos and Shobert.[10] This also follows from Fig. 16 of the paper[1] to which we shall refer later.

Bearing this in mind is helpful in the interpretation, e.g., of Figs. 11 and 12, representing starting and running friction, of which the latter must necessarily show a greater influence of viscosity effects. Furthermore, it would be of interest to know to which oil Figs. 11 to 14 refer or whether different oils showed

any difference, which probably was not the case. This once more tends to show that (1) viscosity effects are rather strong in all these experiments and (2) that the behavior of the bearing materials is largely determined by properties of these materials which are not taken into account by the concepts at which the introduction hints.

The writer would be inclined to interpret the running properties as they appear in the experiments, as determined by interlocking of asperities,[6] cold work, and Coulomb friction between the metal surfaces, contaminated in some not necessarily predictable way. Chromium and stainless steel will certainly be contaminated by a surface layer of oxygen or oxide (passivity).

The well-known properties of pure silver may perhaps throw some light on the interpretation of Fig. 13 showing the outstanding low starting friction of silver. Silver is the only strictly homogeneous and ductile bearing metal tested. All others contain hard components. Moreover silver is certainly the least reactive at local high temperatures. In running friction tests under the conditions of experiment one would qualitatively expect a larger contribution by fluid friction with the less homogeneous and less ductile metals. Such a metal should actually bear at fewer points and thus permit more easily the formation of a bearing wedge of the lubricant. As a result, the bearing friction would fall in comparison with silver. Attempting and further testing such interpretations is of vital importance for the practical application of the paper. Possibly the order of the curves of Fig. 11, i.e., strictly reverse order of starting friction and hardness, may be largely determined by the same phenomenon. Unfortunately the surfaces of the bearings have not apparently been examined microscopically. In view of the wear of the journals there must be surface changes.

Regarding Fig. 16, the curves of running friction go with the oil viscosities, which shows once more that fluid lubrication predominates under these conditions and that the method of lubrication used still amply feeds lubricant. The same order of the oils appears in starting friction up to 75 lb per sq in. from which it follows that up to this pressure fluid lubrication definitely predominates—at least in this bearing combination. At higher pressures castor oil shows the behavior one would expect in nonfluid lubrication.

Those who attribute particular significance to the wetting power of oils might be reminded of the good performance of chromium-plated and stainless-steel journals which are certainly only poorly wetted.

R. SCHNURMANN.[11] The authors' tests were made with loads of from 25 to 140 lb and at sliding speeds of 203.2 cm per sec. A thermocouple was inserted in the middle of the bottom half of the bearing "as close as possible to the bearing surface." The highest temperature thus measured was 64 C, when a monel-metal journal was running at a load of 140 lb (i.e., 63,560 gram weight) in a tin-base babbitt bearing, and castor oil was used as lubricant. It would be interesting to have a more detailed description of the location of the thermocouple and to know as closely as possible its actual distance from the bearing surface.

The melting point of the tin-base babbitt is about 232 C, and it does not seem likely that a temperature gradient of about 168 C can be maintained in the mass of the bearing metal over a very short distance from its surface. The assumption of "high localized temperatures" on a metal surface with asperities of a height of certainly less than 5×10^{-4} cm is not plausible whatever the geometrical shape, cylindrical or pyramidal, of the surface asperities may be through which the heat of friction is conducted away. It appears that if any "wiping" of the bearing metal occurred it could only be effected by the normal rise of bearing temperature, which the authors have measured, but not by imaginary considerably higher "localized temperatures," the occurrence of which the high values of the heat conductivity of metals exclude.

AUTHORS' CLOSURE

In connection with J. L. Fletcher's questions, the authors are of the definite opinion that the value of the coefficient of friction for the same "zero-roughness" surface will not be the same for all types of metals. This is due to such physical properties of an oil as its affinity to various surfaces corresponding to different degrees of adsorption. Experimentally this was demonstrated[12] by placing a drop of oil directly on the line of contact of equally well polished surfaces of different materials M_1 and M_2, Fig. 2 of this closure. As may be seen from the sketch, the drop T assumes an unsymmetrical position between M_1 and M_2 due to higher affinity to M_1 than to M_2.

The questions raised by both J. R. Connelly and Paul G. Exline are very important. Did the bearings perform in the region of boundary friction? The testing machine used was built for boundary conditions of friction. We notice the low L/D value, which is equal to 0.736. The short bearing is not provided with any circumferential sealing grooves and, therefore, the side

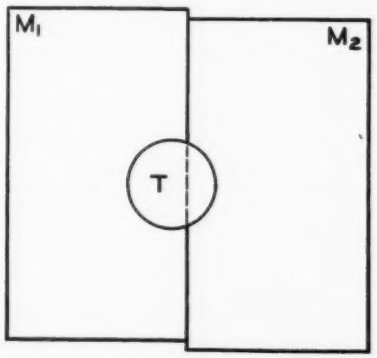

FIG. 2 AFFINITY OF OIL TO DIFFERENT METAL SURFACES

leakage is very large. The oil supply was never maintained higher than 10 drops per min. Finally, the fact that the roughness diminished during tests serves to indicate that the rubbing surfaces were never separated by a continuous film.

Fig. 1 of Mr. Exline's discussion shows the calculated values of ZN/P which suggests that the bearing performs in the region of perfect fluid lubrication. Referring to such curves, we might deduce somewhat confusing conclusions. For example, consider oil-lubricated steel-mill bearings. Some of these operate with values of ZN/P less than 2 (Z = 250 cp, N = 40 rpm, and P = 2500 lb per sq in.). A mirror-finish journal runs in such a bearing with a continuous film of oil, without any wear. However, if one refers to the value of ZN/P equal to 2 it might appear that such a bearing could not perform at all because it is too close to the region of dry friction.

In view of this fact, it is possible that fluid-film lubrication was also taking place during the experiments, but the bearings were performing predominantly in the region of boundary or semi-fluid friction.

It is interesting to note from F. P. Bowden's remarks the fact that sliding between metal surfaces might not be a continuous process. This was found to be the case during laboratory experiments with the use of flat contact surfaces. Undoubtedly

[12] "Über die Messung der Schmierfähigkeit von Schmierölen," by Richard von Dallwitz-Wegener, *Zeit. technische Physik*, vol. 5, 1924, pp. 378–384.

similar performance might occur in cylindrically shaped surfaces, i.e., standard circular bearings.

Dr. S. Kyropoulos indicates the possibility that the experiments were carried out under conditions of mixed nonfluid (boundary) and fluid lubrication. His explanation of the low starting friction of silver bearings is interesting.

The authors believe that their work will give an impetus for similar correlation of friction and surface-finish data. Developed surface-finish apparatus provide complete facilities for such accurate measurements. Friction versus finish data will undoubtedly constitute a field for further development in laboratories and in industry. In this connection, the collaboration of physicists and engineers will prove very beneficial in elucidating the complex phenomena of friction which some authors consider close to the "terra incognita."

A Photoelastic Study of Stresses in Rotating Disks[1]

C. W. MacGregor.[2] The author has presented an interesting study of the stresses in rotating disks containing holes by applying the newer three-dimensional stress-freezing technique to what is essentially a two-dimensional problem.

A question which occurred to the writer, however, concerns the ratio of the diameter of the holes used to the thickness of the plate. In model tests A and B the diameter-thickness ratios are 0.5 and 0.75, respectively, according to the data given in the paper. This means that the problem falls somewhere between the cases of plane strain and plane stress.

It was shown some time ago by R. W. Vose[3] that a considerable reduction in the stress-concentration factor determined photoelastically was found for the case of a hole in a plate subjected to tension in one direction, as compared to the theoretical value when the ratio of hole diameter to the thickness of the plate was less than 2 to 1. This would seem to indicate that the stresses found photoelastically in the case of the rotating disks described in the present paper are lower than the actual values. Although a direct numerical correction based upon Vose's values, as applied to the case under discussion, may not give the true picture, it is indicative of the order of magnitude of the effect. The factors by which the photoelastic-stress value should be multiplied to obtain the theoretical value in the case of the plate with a single hole subjected to tension in one direction only would be 1.305 and 1.167, respectively, for the diameter-to-thickness ratios used in model tests A and B of the paper.

The writer would like to ask the author if any experiments were made to determine whether or not such effects were of appreciable magnitude in the present tests.

A. Yorgiadis.[4] Referring to Equation [4a] of the paper and the preceding paragraph, the ratio of the cross-sectional area, along the circle of centers before drilling the holes, to the area after drilling is not

$$\frac{2\pi a}{2\pi a - 6d} \quad \ldots\ldots [5] \quad \text{but} \quad \frac{2\pi}{2\pi - 24 \arcsin (d/4a)} \quad \ldots\ldots [6]$$

Even this corrected expression would be unsuitable for this purpose because the maximum reduction in area does not occur in the line of centers, but in the circle, the radius of which is $\sqrt{a^2 - 0.25\,d^2}$ and at that section the reduction in area due to drilling is

$$\frac{2\pi}{2\pi - 12 \arcsin \dfrac{d}{2a}} \quad \ldots\ldots [7]$$

When d is small relative to a, the author's equation introduces only a slight error. However, this error becomes appreciable as this ratio increases. For example when $a = 1$ in. and $d = {}^3/_8$ in., Equation [7] of this discussion gives a value 0.3 per cent more than Equation [5]. When $a = 1$ in. and $d = {}^7/_8$ in., Equation [7] gives a value 23 per cent more than Equation [5]. At the limiting value, $d = a$, when the drilled holes are tangent to each other, the author's equation yields $\dfrac{\pi}{\pi - 3}$, whereas this value should be $\dfrac{\pi}{\pi - \pi}$, or ∞ as calculated from Equation [7].

Author's Closure

Referring to the corrections suggested by Dr. MacGregor, the author wishes to state that no such corrections were made because none was believed necessary. It seems to the author that Vose's experimental results have been seriously misinterpreted by a number of photoelasticians. Although it is not defined in Vose's article, the quantity which he has called the "stress-concentration ratio" seems to be the ratio of the change of thickness at the point of highest stress to the change of thickness at a point in the uniform stress field. Customary usage would define the stress-concentration factor in the problem of the hole in a tension field as the ratio of the maximum principal stress to the tension in the uniform field. The two definitions will yield identical values as long as a condition of plane stress exists in the plate. However, when the ratio of the diameter of the hole to the thickness of the plate is small the stress system in the plate is three-dimensional and the strain gage does not measure the sum of the two principal stresses in the plane of the plate. Theory of elasticity shows that the stress-concentration factor is equal to 3 for the limiting cases of plane stress and plane strain and there is no apparent reason to anticipate an appreciable change in the intermediate range. Some unpublished experimental results (obtained optically, by use of a polariscope) of M. M. Frocht confirm this opinion.

In the problem of the rotating disk the variation of the body forces causes a difference in the theoretical solutions under the assumptions of plane stress and plane strain. It is well known that the drilling of a small hole in the center of a solid rotating disk of uniform thickness doubles the maximum principal stress in the disk. Although this stress-concentration factor is usually derived under the assumption of plane stress, it is equally correct for the case of plane strain, despite the difference in the magnitudes of the stresses in the two cases. There is no available theoretical solution for the problem dealt with experimentally in the author's paper, but, in the light of the foregoing considerations, it seems reasonable to assume that the correction suggested by Dr. MacGregor is unwarranted.

The author readily concedes that Mr. Yorgiadis' mathematics is correct. At the time of writing of the paper the approximate nature of the correction factor, Equation [5], was recognized, but this form was used for the sake of simplicity. The 0.3 per cent error involved is considerably smaller than the probable experimental error. In the extreme hypothetical cases cited by Mr. Yorgiadis not even his "corrected" correction factors would be suitable, because the assumption stated in the paper, upon which the use of the correction factor is based, is grossly violated.

Book Reviews

Strength of Marine-Engine Shafting

STRENGTH OF MARINE-ENGINE SHAFTING. By S. F. Dorey, D.Sc., Chief Engineer Surveyor, Lloyd's Register of Shipping. A paper with copious discussion published by the North-East Coast Institution of Engineers and Shipbuilders, Newcastle-on-Tyne, England, 1939. Cloth, 6 × 9 in., 150 pp., figs., 5 s.

REVIEWED BY J. P. DEN HARTOG[1]

THE paper gives a very elaborate and complete account of the cause and frequency of failures of marine shafting during the last decade. It can be divided roughly into three parts: The first deals exhaustively with the various strength properties of materials used in crankshafts, the second part is concerned with torsional vibration in the drive system, and the third part discusses axial vibration.

It has been found, in the author's experience, that a number of failures in crankshafts could not be explained by torsional excitation, but would have to be traced down to a longitudinal or axial vibration of the entire drive structure. Methods of analysis for calculating these effects, very similar to those employed for torsional vibrations, are given. The method used throughout the paper is the usual one originated by Holzer. An innovation consists in writing the hysteresis loss in the shaft as being proportional to the square of the stress rather than to the 2.3 power, which has been common practice heretofore. The history of this number 2.3 is rather interesting. It appears that tests prior to 1920 by an English investigator on mild steel gave a hysteresis loss proportional to the 2.3 power of the stress. Modern crankshaft steels have hysteresis losses several times smaller than those found by the original investigator and, moreover, the total loss in the engine is about ten times as high as the hysteresis loss in the crankshaft. Nevertheless, it has become customary to calculate the hysteresis loss in the crankshaft on the basis of the power 2.3 and then to multiply by an empirical constant of roughly 10. This procedure surprisingly leads to results that are in decent agreement with practice, but an analysis on the basis of the simple power 2 would do just as well and is very much simpler to handle. It is gratifying therefore that an authority on Lloyd's Register of Shipping has taken the initiative toward this simplification.

The paper is illustrated with a large number of records and test setups and the discussion contains contributions from almost every authority in the field of vibrations in marine engines.

Biomechanics

RESEARCHES IN THE BIODYNAMICS OF LOCOMOTION. N. Bernstein, editor. Volume 1, V.I.E.M. (Institute of Experimental Medicine), U.S.S.R., 1935. 243 pp., 107 figs., 88 tables. $2.00 (Rbls. 7.75) (Russian).

FEARFULLY AND WONDERFULLY MADE. By Renée von Eulenburg-Wiener. The Macmillan Company, New York, 1938. Cloth, 6 × 9½ in., xii and 472 pp., $3.50.

REVIEWED BY GEORGE B. KARELITZ[2]

THE word "biomechanics" is now rather fashionable. It denotes the active interest which medical people have recently shown in studying the mechanics of the human body, in addition to the chemistry of the thousands of involved reactions in our organisms.

The analysis of the mechanics of the human body should be basically easier than the study of the physiological reactions, nevertheless exact information in biomechanics is scarce. This may be attributed to the fact that mechanical models and adequate instruments are expensive when compared with the equipment necessary for biological and chemical investigations.

The mechanics of the body can be studied from various angles and the term biomechanics is really too all-inclusive as used at present. In the first place, the body can be considered as a machine designed to perform certain mechanical motions and produce mechanical work. The kinematics of the various linkages; both static and dynamic forces acting on the various members and joints of the body; the stresses and strength of the structural bones, muscles, and tendons would fall under this classification. Then the heat balance of the body may be analyzed. This would involve the conversion of energy of combustion and of all the complicated reactions into heat and work, i.e., consideration of the body as a power generator. Again, the control systems of the body can be studied: the thermostatic function of the skin, the optical, acoustical, and muscular mechanisms, and the flow of blood through the vessels.

The first book, although somewhat old for a book review, is hardly known here. It is the first treatise in a series devoted to human locomotion, and deals with the walking of an adult. The locomotion of a child, the military step, the dynamics of running, and the motion on protheses are promised in the next volume. The reports published in this volume are the results of ten years of experimentation by Bernstein and his group; the technique used was a substantial improvement upon the methods employed by Braune and Fischer.[3] A number of small lamps were attached to various joints of the investigated men, and photographs at the rate of 98 frames per sec were taken of the lamps' positions while the men walked. After careful time plotting of the coordinates so determined, the velocities and accelerations of the points were determined and, therefore, the dynamic forces acting on the various joints could be ascertained.

For instance, the velocity of the shoulder in a normal man was found to vary from 4.7 fps to 5.9 fps during each step, while the pressure of his foot on the ground varied from 90 to 213 lb. The weight of the man was 152 lb and his speed was 122 paces per min.

The first two chapters of the book describe the experimental technique. Chapter 3 treats the free walking of an adult; chapter 4 gives the information for a laborer carrying loads; the last chapter discusses fatigue after long walking, both free and with load.

The book of Eulenburg-Wiener is of interest to those who would consider the human body as a power generator. In a short volume "the author has succeeded in presenting and explaining the most important facts now known about the human body." The book consists of 32 chapters. The first several chapters deal with the digestion of food, its chemical transformations, and absorption while it travels through the body.

Four chapters discuss the blood-circulation system. The pressure drop of from 30 to 40 mm of mercury in the capillary system is discussed; the mechanics of blood vessels as described

[1] Associate Professor of Applied Mechanics, Harvard University, Cambridge, Mass. Mem. A.S.M.E.

[3] "Der Gang des Manschen," by O. Fischer, Trans. Society of Saxony, Teubner, Leipzig 1895; 1899–1901, 1904.

is somewhat confused; it would offer a challenging problem for one interested in variable flow in elastic tubes.

The energetics of the body is treated in several chapters. It is rather remarkable that the animal body produces the same amount of heat during the digestion of a given food, such as carbohydrates or true fat, as the food would yield if burned in a bomb calorimeter. Yet the temperatures at which all the reactions are taking place are so much lower than any which are used in laboratories.

The importance of the skin as an instrument for regulation of the body temperature is pointed out in chapter 28. Minute areas respond to either hot or cold sensations. These spots are sensitive to infrared radiation lying within the range of from 8000 to 1,000,000 A. The last chapter gives an integrated picture of the human body as a whole, surveying the various sensations and activities in their interconnections.

The book leaves one with the impression that enormous strides were made toward understanding the fine physiological reactions and interrelations in the many complicated organisms comprising the human body. In comparison, the lack of information on the simple mechanics of the body is striking. Thirty years passed between the work of Braune and Fischer and that of the Bernstein group. Some published work on testing tendon tissues for strength is of very recent origin.[4,5] An indication that the wings of birds, a duck, and a hawk are constructed with the factor of safety of two was obtained in 1938 in the State Aeronautical Research Laboratory at Moscow. Other scattered bits of information can be found here and there. It seems that it is time for such organizations as the powerful insurance companies to take up the subject of biomechanics, find a number of able engineers and physicians genuinely interested in the mechanics of the human body, and let them work on a long-time program. The result of such an investigation, properly endowed and planned, would no doubt repay manyfold the investment of funds and energy involved in the investigation of this neglected field.

Vapor Charts and Special Tables for Turbine Calculations

VAPOR CHARTS AND SPECIAL TABLES FOR TURBINE CALCULATIONS. By Frank O. Ellenwood and Charles O. Mackey, Professors of Heat Power Engineering, Cornell University, John Wiley & Sons, Inc., New York, N. Y., 1939. Cloth, 8½ × 11 in., 43 pages, charts, tables. $2.50.

REVIEWED BY C. HAROLD BERRY[6]

THE original Ellenwood steam charts, based upon the Marks and Davis tables, appeared in 1914, and rapidly gained favor among engineers having occasion to make frequent computations for changes of state of steam. This replotting uses the Keenan and Keyes tables and therefore covers a wider range with superior accuracy. The plotting and reproduction are splendidly done.

The chart giving the properties of saturated and superheated steam covers a wide range to a large scale. If it were on one sheet, it would be 40 × 47 in. For convenience, it is divided into twenty-one sections, each occupying one page of the volume. Once the user is familiar with the arrangement (a matter of a few minutes' examination) he should find this volume much more convenient and durable than a large "blanket" chart. A small-scale skeleton chart serves as an index which will be used at first and soon outgrown.

The ordinate scale of enthalpy is divided to single Btu per pound; fractions can be estimated. The abscissa is a logarithmic scale of specific volume comprising five 9-inch cycles with divisions not as close as those of the 10-inch slide rule; readings can be estimated to three digits throughout the range from the critical volume (0.05) to 3500 cu ft per lb, which is a trifle larger than the specific volume of saturated vapor at 32 F.

Lines of constant pressure, constant entropy, constant per cent moisture (in the wet region), and constant temperature (in the superheated region) are provided at satisfactory intervals, wide enough to make the chart easy to read, and close enough to permit estimating between consecutive curves to a degree of precision that agrees well with the probable accuracy of observed data.

The choice of enthalpy and volume as coordinates provides what is probably the most widely useful chart of vapor properties. Since specific volumes can be read directly, in addition to all the quantities given by the widely used Mollier enthalpy-entropy chart, the Ellenwood chart makes possible a direct solution in terms of ratio of expansion which demands a tedious cut-and-try solution by other means. The chart may appear at first sight to be somewhat more complex, but this impression is soon dispelled.

One could wish that the authors had found it feasible to provide a generous overlap on all four edges of each section of the chart. Apart from this minor item, one can find no fault with the chart, which should promptly resume its place as the most convenient means for carrying out steam computations with a degree of accuracy sufficient for most applications.

The chart giving the properties of compressed liquid water is the best that the writer has seen. It provides for direct solution of all types of problems that arise, and permits reading to a degree of accuracy that is as good as the readings of thermometers and pressure gages. It is much more convenient and more accurate than the skeleton table which is the only other convenient source of data in this field. This chart, covering two pages, is a valuable contribution to the engineer's equipment.

Supplementary tables and charts greatly increase the usefulness of the volume. For the turbine designer there are tables of jet velocities for enthalpy drops up to 80 Btu by tenths, and up to 599 by units, and a table of squares of numbers from 200 to 2000, expressed in millions. For the air conditioner there are three pages of psychrometric charts for dry-bulb temperatures from —40 to +350 F, plotted in convenient form so as to yield easy readings of relative and specific humidity, volume per pound of air, and the sigma function (enthalpy — enthalpy of liquid). For the refrigerator there are charts of the properties of ammonia and freon-12, with enthalpy plotted against the logarithm of pressure, covering the entire two-phase liquid-vapor region and an adequate portion of the superheated-vapor region. For everybody there are tables for correcting mercurial barometer readings for gravity, temperature, and capillarity.

This replotting of a chart that has always been one of the most useful should meet with a hearty welcome from engineers and others who have occasion to make thermodynamic computations. The authors are to be congratulated for having produced so good a job.

In a publication involving so much plotting, it is astonishing to find so few errors. There are seven errors in marking numerical values on the lines—these will be immediately evident to the user of the chart—five of them are noted on an errata sheet.

WARREN H. McBRYDE
1939-1940

Warren Horton McBryde

Warren Horton McBryde, consulting engineer, industrialist, and world traveler, of San Francisco, California, President of The American Society of Mechanical Engineers for the year 1939-1940, was born at Mobile, Ala., in 1876. At the age of 17, he entered the Alabama Polytechnic Institute, Auburn, where he specialized in electrical and mechanical engineering. He was graduated in 1897 with the degree of B.S.

Immediately after graduation, he was employed by the Electric Lighting Co. of Mobile, following which he did architectural designing and drafting for George F. Barber & Co., Knoxville, Tenn. During the Spanish-American War, he served for a few months in the U.S. Lighthouse Department and U.S. Engineers Corps and had charge of the submarine mines, searchlights, and electrical equipment guarding the entrance to Mobile Bay. Following this he was made chief electrician of the U.S. Army Transport *Sheridan*, on which he made a voyage from New York, N.Y., via the Suez Canal to the Philippines; thence via Nagasaki, Japan, to San Francisco, where he was honorably discharged. From 1899 to 1903, Mr. McBryde was employed by the Yuba Electric Power Company as assistant resident engineer in charge of construction on the Colgate hydroelectric powerhouse, in northern California, by the Peyton Chemical Company, San Francisco, as assistant superintendent of construction and by the Bay Counties Power Company, also of San Francisco, as chief draftsman and assistant to the chief electrical and mechanical engineer.

He was the first resident engineer in charge of construction at Gibbstown, N.J., for the E. I. du Pont de Nemours Powder Company from 1903 to 1905, and was transferred during the year 1905 to Hercules, Calif., where he constructed large sulphuric acid plants. In 1906, he was appointed the first chief of the West Coast engineering and construction department of the du Pont organization and, subsequently, became assistant superintendent of its Hercules plant and retained this position until 1919. During this period, Mr. McBryde was in charge of all maintenance and repairs, and handled many important engineering problems in connection with the hurried construction of 12 large TNT plants, the necessary nitric- and sulphuric-acid factories, and many other industrial buildings during the World War. He was also in charge of the labor- and industrial-relations department of the company and secured positions for more than three quarters of the 4000 men under his supervision when demobilization came.

In 1919, he became secretary of the California & Hawaiian Sugar Refining Co., San Francisco, and assistant to the general manager, and handled many important engineering problems for the company until 1927, when he engaged on his own account in his present business as a consulting engineer.

Mr. McBryde was elected a member of the Society in 1921. He was chairman of the San Francisco Section in 1925 and 1926, when the Spring Meeting was held in San Francisco in the latter year. As a delegate from the Section, he attended the 1926 Annual Meeting of the Society in New York, N.Y., and the celebration at Washington, D.C., in 1930, of the fiftieth anniversary of the formation of the A.S.M.E.

In company with Calvin W. Rice, Mr. McBryde represented the Society at the 75th anniversary of the Verein deutscher Ingenieure at Cologne, Germany, in June, 1931; he also attended the 1931 and 1935 spring meetings in England of The Institution of Mechanical Engineers at Cambridge and Bath, respectively. He was one of the founders of the Engineering Societies Employment Service office in San Francisco. In 1937, Mr. McBryde was elected vice-president of the A.S.M.E. and in his official capacity attended the 1937 and 1938 Annual Meetings in New York. He has taken a great deal of interest in the activities of A.S.M.E. student members and has attended their meetings at several schools on the West Coast as well as the Student Group Meetings, in 1938 and 1939, at Los Angeles and San Francisco, respectively.

In more recent years Mr. McBryde made his second and third circumnavigations of the globe, including voyages which took him through the Suez and Panama Canals, the Strait of Magellan and around the Cape of Good Hope, and visited and studied some eighty of the most prominent countries of the world, some two hundred and fifty of the most important world ports, and the capitals and principal cities of most of these countries.

These extended trips were made to study first-hand the engineering progress and industrial developments, the harbor improvements and port facilities, the transportation systems—rail, highways, and inland waterways—also the industrial, mineral, and agricultural products of these countries, as well as their domestic commerce and foreign trade, their economic conditions, and their political problems. During these trips he met many of the world's leading engineers and the directors of the most important museums of science and industry.

Other activities of Mr. McBryde include election as mayor of Hercules, Calif., and supervisor of Contra Costa County, while a resident of that city; the San Francisco Engineers' Club; the San Francisco Electrical Development League; and the presidency of the Industrial Association of San Francisco, in 1921, in recognition of his experience as an industrial employer and his interest in workingmen.

The American Society of Mechanical Engineers

HEADQUARTERS: 29 West 39th St., New York, N. Y.
MID-WEST OFFICE: Room 1617, 205 West Wacker Drive, Chicago, Ill.
MID-CONTINENT OFFICE: 211 Midco Building, Tulsa, Okla.

The members of the Council and of its standing and special committees given on the following pages are those in office on January 1, 1940, serving for the official year 1939–1940. The terms of office of members of other committees are not fixed by the official calendar.

BALTIMORE

Organized: 1916
Territory: Radius of thirty miles from Baltimore, Md.
Place of Meeting: Engineers Club of Baltimore
Luncheon meeting every Wednesday at 12:00 noon at Engineers Club
Number of Members: 189

EXECUTIVE COMMITTEE

L. F. COFFIN, *Chairman*
S. B. SEXTON, 3RD, *Secretary-Treasurer*
W. D. BOYNTON

BIRMINGHAM

Organized: 1915
Territory: Radius of sixty miles from Birmingham, Ala.
Place of Meeting: Tutwiler Hotel
Number of Members: 90

EXECUTIVE COMMITTEE

R. A. POLGLAZE, *Chairman*
H. S. KENT, *Vice-Chairman*
C. F. VON HERRMAN, JR., *Secretary-Treasurer*
J. E. GETZEN
W. JOE MOORE

BOSTON

Organized: 1909
Territory: Radius of thirty miles from Boston, Mass.
Place of Meeting: Mass. Inst. of Technol
Local Organization: Engineering Societ of New England
Number of Members: 559

BOSTON

(*Continued*)

EXECUTIVE COMMITTEE

EDGAR MACNAUGHTON, *Chairman*

D. E. STEER, *Secretary-Treasurer*

BUFFALO

Organized: 1915
Territory: Radius of thirty miles from Buffalo, N.Y.
Place of Meeting: University Club, Delaware Ave.
Local Organization: Engineering Society of Buffalo
Number of Members: 191

EXECUTIVE COMMITTEE

W. M. KAUFFMANN, *Acting Chairman*
E. J. WEITZMAN, *Acting Vice-Chairman*
W. A. MILLER, *Secretary*
C. E. HARRINGTON, *Treasurer*
PAUL DUBOSCLARD
C. G. ROSE
J. L. YATES, *Adviser for Juniors*

CENTRAL ILLINOIS

Organized: 1937
Territory: All the territory in Central Illinois between the following counties on the northern boundary: Bureau, LaSalle, Knox, Stark, Putnam, Marshall, Livingston, Peoria; counties on the southern boundary: Pike, Scott, Morgan, Sangamon, Macon, Piatt, Douglas, and Edgar
Place of Meeting: Hotel Pere Marquette or Caterpillar Show Room
Number of Members: 94

EXECUTIVE COMMITTEE

E. D. EDWARDS, *Chairman*
O. A. LEUTWILER, *Vice-Chairman*
F. L. MEYER, *Vice-Chairman*
C. O. SMITH, *Vice-Chairman*
R. T. MEES, *Secretary-Treasurer*
L. E. JOHNSON, *Assistant Secretary*

JUNIOR GROUP

L. E. JOHNSON, *Chairman*

CENTRAL INDIANA

Organized: 1916
Territory: Radius of eighty miles from Indianapolis, within Indiana
Place of Meeting: Place varies
Local Organization: Indiana Engineering Society
Number of Members: 123

EXECUTIVE COMMITTEE

HANS SKABO, *Chairman*
J. A. DROGUE, *Vice-Chairman*
W. J. COPE, *Secretary-Treasurer*
E. A. GRIMMER
C. M. GROSS
RONALD UPDIKE
CARL WISCHMEYER

CENTRAL PENNSYLVANIA

Organized: 1921
Territory: Radius of approximately sixty miles from State College, Pa.
Place of Meeting: State College and Altoona, Pa.
Number of Members: 85

EXECUTIVE COMMITTEE

F. C. STEWART, *Chairman*
J. O. P. HUMMEL, *Secretary-Treasurer*
C. L. ALLEN
W. D. GARMAN
G. L. GUILLET

CHARLOTTE

Organized: As a Branch, 1923; as a Section, 1927
Territory: Radius of seventy-five miles from Charlotte, N.C.
Luncheon Meeting every Monday at 1:00 p.m. at Efirds Department Store Dining Room
Local Organization: Charlotte Engineers Club
Number of Members: 37

EXECUTIVE COMMITTEE

W. W. LEROY, *Chairman*
R. P. REECE, *1st Vice-Chairman*
M. D. THOMASON, *2nd Vice-Chairman*
A. W. DUNBAR, *3rd Vice-Chairman*
J. S. BASS, JR., *Secretary-Treasurer*
A. W. BOLLENBACK
T. C. HEYWARD
ASA HOSMER
W. E. MCDOWELL
T. O. SILLS

CHICAGO

Organized: 1913
Territory: Radius of fifty miles from Chicago, Ill.
Headquarters: Mid-West A.S.M.E. Office, Room 1617, 205 West Wacker Drive, Chicago, Ill.
Place of Meeting: Civic Opera Bldg., 20 N. Wacker Dr.
Luncheon Meeting every Tuesday at 12:15 p.m. at Chicago Engineers' Club
Local Organization: Western Society of Engineers
Number of Members: 784

EXECUTIVE COMMITTEE

L. M. ELLISON, *Chairman*
H. M. BLACK, *Vice-Chairman*
F. C. EVERITT, *Vice-Chairman*
H. F. HEBLEY, *Vice-Chairman*
D. ROESCH, *Vice-Chairman*
F. B. ORR, *Secretary-Treasurer*
C. C. AUSTIN
A. D. BAILEY
C. L. CHARLES
W. E. DUNHAM
J. A. FOLSE
A. H. JENS
J. S. KOZACKA
R. KRAUSE
F. H. LANE

J. C. MARSHALL
T. S. MCEWAN
J. R. MICHEL
H. L. NACHMAN
C. W. PARSONS
H. S. PHILBRICK
J. G. REID
C. ROBERTS
M. W. SHERWOOD
B. D. STEVENS
R. E. TURNER
C. L. WACHS

JUNIOR GROUP

R. KRAUSE, *Co-Chairman*
J. C. MARSHALL, *Co-Chairman*

CINCINNATI

Organized: 1912
Territory: Radius of thirty miles from Cincinnati, Ohio
Place of Meeting: Engineers' Club Rooms, Ninth & Race Sts.
Local Organization: Engineers' Club of Cincinnati
Number of Members: 185

EXECUTIVE COMMITTEE

E. H. SCHUBERT, *Chairman*
C. E. SOMOGYI, *Vice-Chairman*
J. W. BUNTING, *Secretary-Treasurer*
H. B. BRANDT
D. S. BROWN

CINCINNATI

(Continued)

A. G. Bruck
E. J. Martin
L. E. Nenninger
E. S. Sauerbrunn
C. H. Spiehler
H. P. Thompson

CLEVELAND

Organized: 1918
Territory: Counties of Lorain, Cuyahoga Lake, Geauga, and Ashtabula in Ohio
Place of Meeting: Case Club or Cleveland Engineering Society Rooms
Local Organization: Cleveland Engineering Society
Number of Members: 248

Executive Committee

G. B. Carson, *Chairman*
E. L. Lindseth, *Vice-Chairman*
E. R. McCarthy, *Secretary*
F. A. Barnes, *Treasurer*
A. B. Einig
E. B. Heavilon
J. M. Main
H. A. Schwartz
D. K. Wright

Junior Group

R. E. Erickson, *Chairman*
W. A. Lynam, *Secretary-Treasurer*
J. O. Geissbuhler

COLORADO

Organized: 1919
Territory: Entire State of Colorado
Place of Meeting: Parisienne Rotisserie Inn, Denver, Colo.
Local Organization: Colorado Engineering Council (Colorado Society of Engineers)
Number of Members: 77

Executive Committee

A. L. Hill, *Chairman*
R. F. Throne, *Secretary-Treasurer*
C. E. Beatty
L. D. Crain
F. H. Prouty
G. A. Richter
S. L. Simmering
J. Tayler Strate

COLUMBUS

Organized: 1920
Territory: Counties of Union, Delaware, Licking, Madison, Franklin, Fayette, Pickaway, and Ross in Ohio
Place of Meeting: Battelle Memorial Institute and The Ohio State University
Local Organization: Engineers' Club of Columbus
Luncheon Meeting third Friday of each month at 12:00 noon at Engineers' Club, Columbus
Number of Members: 76

Executive Committee

R. N. Tucker, *Chairman*
E. M. Sampson, *Vice-Chairman*
R. C. Cross, *Secretary-Treasurer*
H. N. Booker
A. I. Brown
H. R. Limbacher
C. P. Roberts
W. A. Welcker, Jr.

DAYTON

Organized: 1926
Territory: Counties of Drake, Miami, Champaign, Preble, Montgomery, Greene, and northern part of Butler and Warren in Ohio
Place of Meeting: Engineers' Club of Dayton
Local Organization: Engineers' Club of Dayton
Number of Members: 82

Executive Committee

P. H. Kemmer, *Chairman*
A. R. Weber, *Vice-Chairman*
(Miss) M. Elsa Gardner, *Secretary*
B. W. Treadwell, *Treasurer*
C. L. Bauer
H. M. Gano
R. W. Martin
T. F. Rataiczak
W. E. Sooy

DETROIT

Organized: 1916
Territory: Radius of thirty miles from Detroit, Mich.
Place of Meeting: Place varies
Local Organization: Engineering Society of Detroit
Number of Members: 456

Executive Committee

B. W. Beyer, Jr., *Chairman*
Tom Jeffords, *Secretary-Treasurer*
E. J. Abbott
J. A. Carlin
M. L. Fox
J. F. Jarnagin
J. B. Macauley
D. E. McGuire
Jesse Ormondroyd
J. P. Schechter
A. M. Selvey
M. W. Benjamin, *Ex-Officio*

Junior Group

George Scranton, *Chairman*
Clarence Green, *Secretary*
B. W. Lane

EAST TENNESSEE

Organized: 1922
Territory: All counties in Tennessee east of the west boundary of Scott, Morgan, Cumberland, White, Warren, Coffee, Moore, Franklin; Belle County in Kentucky; and Rossville, Dade, Walker, Cattasa, Whitfield, Murray, Gordon, Chattooga in Georgia
Place of Meeting: Place varies
Local Organization: Chattanooga Engineers Club and Knoxville Technical Club
Luncheon Meeting every Monday noon at Chattanooga Engineers Club
Number of Members: 94

Executive Committee

W. R. Chambers, *Chairman*
T. C. Ervin, *1st Vice-Chairman*
David Shearer, *2nd Vice-Chairman*
R. B. Taylor, *3rd Vice-Chairman*
J. M. Tucker, *Secretary*
G. E. Campbell
C. E. Ferris
J. M. Johnson
Elmer Torok
A. S. Wells

ERIE

Organized: 1917
Territory: Radius of thirty miles from Erie, Pa.
Place of Meeting: Auditorium of Pennsylvania Telephone Company
Number of Members: 75

Executive Committee

C. T. Oergel, *Chairman*
G. F. Linde, *Vice-Chairman*
R. R. Blunt, *Secretary*
E. E. Ims, *Treasurer*
G. W. Bach
E. H. Horstkotte
W. L. Hunter
McD. S. Reed
R. W. Rogers

FLORIDA

Organized: 1925
Territory: State of Florida
Place of Meeting: Various Cities in State
Local Organization: Florida Engineering Society, Gainesville, Fla.
Number of Members: 74

Executive Committee

N. C. Ebaugh, *Chairman*
J. H. Clouse, *1st Vice-Chairman*
M. H. C. Brombacher, *2nd Vice-Chairman*
V. C. Couchman, *Secretary-Treasurer*
W. E. Drew
A. B. Hale
W. A. Stansfield
C. H. Stanton, *Student Branch Chairman*

FORT WAYNE

Organized: 1939
Territory: Counties of LaGrange, Steuben, Noble, DeKalb, Whitley, Allen, Wabash, Huntington, Wells, Adams, Miami, Blackford and Jay in Indiana; Counties of Williams, Defiance, Paulding, Van Wert and Mercer in Ohio
Local Organization: Fort Wayne Engineers' Society
Number of Members: 27

Executive Committee

N. T. Bourke, *Chairman*
W. L. Knaus, *Vice-Chairman*
F. T. McInerney, *Secretary*
F. L. Ruoff, *Treasurer*
J. H. Powers
W. S. Richhart

GREEN MOUNTAIN

Organized: 1923
Territory: Entire State of Vermont and neighboring and closely related communities of Claremont and Hanover, N.H.
Place of Meeting: Springfield, Windsor, Vt., and Claremont, N.H.
Local Organization: Vermont Engineering Society
Number of Members: 39

Executive Committee

M. H. Arms, *Chairman*
Leif Fersing, *Secretary-Treasurer*
P. H. Adams
C. J. Dewell
Douglas Hamilton
J. B. Johnson
E. L. Sussdorff

Junior Group

E. L. Sussdorff, *Chairman*

GREENVILLE

Organized: As a Branch, 1923; as a Section, 1927
Territory: Radius of sixty miles from Greenville, S.C.
Place of Meeting: Meetings held at Greenville, Clemson College, S.C., Canton, Asheville, and Enka, N.C.
Number of Members: 40

Executive Committee

A. D. Asbury, *Chairman*
R. B. Fuller, *Vice-Chairman*
J. H. Sams, *Secretary-Treasurer*
B. E. Fernow
J. R. Gill
H. H. Iler
R. S. Pruitt
J. E. Waldrep

HARTFORD

Organized: 1917, as Branch of Conn. Section; reorganized, 1923
Territory: Hartford County except that portion served by Meriden and New Britain Sections
Place of Meeting: Hartford Electric Light Company
Number of Members: 115

Executive Committee

D. K. Morgan, *Chairman*
H. Burdick, *Vice-Chairman*
R. D. Keller, *Secretary*
S. A. Brandenburg
R. F. Dow
E. P. Herrick
F. O. Hoagland
W. S. Paine
R. S. Shaw
S. J. Teller
G. R. Truedsson
H. B. Van Zelm
J. C. Ward, Jr.

INLAND EMPIRE

Organized: 1921
Territory: East of Columbia River in State of Washington, and Counties of Okanogan and Benton, and part of Northern Idaho
Place of Meeting: Davenport Hotel, Spokane
Luncheons Wednesdays at 12:00 noon, Davenport Hotel, Spokane
Local Organization: Associated Engineers of Spokane
Number of Members: 26

Executive Committee

E. B. Parker, *Chairman*
Alex. Lindsay, *Vice-Chairman*
A. R. Karlsten, *Secretary-Treasurer*
H. F. Gauss
D. R. Gray
H. H. Langdon

ITHACA

Organized: 1936
Territory: Radius of thirty miles from Ithaca plus following cities: Binghamton, Corning, Endicott, Geneva, Painted Post
Place of Meeting: Willard Straight Hall, Cornell Campus, Ithaca, N.Y.
Number of Members: 85

Executive Committee

W. M. Sawdon, *Chairman*
L. C. Wilder, *Vice-Chairman*
F. S. Erdman, *Secretary-Treasurer*
R. E. Kinsman
F. G. Switzer
M. P. Whitney
N. R. Wickersham

KANSAS CITY

Organized: 1921
Territory: Radius of sixty miles from Kansas City, Mo.
Place of Meeting: University Club
Local Organization: Engineers' Club of Kansas City
Number of Members: 135

Executive Committee

E. D. Hay, *Chairman*
H. L. Crain, *Vice-Chairman*
E. M. Bruzelius, *Secretary*
J. R. Stone, *Treasurer*
C. E. Brown
Chester Cotter
M. A. Durland
H. E. Manuel
W. B. Rollins
H. A. Smith
R. V. Sutherland

Junior Group

H. E. Manual, *Chairman*
G. G. Brauninger, *Secretary-Treasurer*
E. M. Bruzelius
R. F. Glore
R. P. Hahn

LOS ANGELES

Organized: 1915
Territory: South of southern boundaries of following counties: Monterey, Kings, Tulares, and Inyo, Calif.
Place of Meeting: Barker Bros. Store
Local Organization: Technical Societies of Los Angeles
Luncheon Meetings Thursdays at 12:00 noon at Engineers' Club
Number of Members: 454

Executive Committee

J. Roy Hoffman, *Chairman*
C. H. Smith, *Vice-Chairman*
E. K. Springer, *Secretary-Treasurer*
P. L. Armstrong
J. C. Brown
D. S. Clark
B. E. Del Mar
S. F. Duncan
A. Hollander
Scott Jensen
J. A. Whitaker

Junior Group

B. E. Del Mar, *Chairman*
O. R. Broberg
R. W. Jones

LOUISVILLE

Organized: 1922
Territory: Radius of thirty miles from Louisville, Ky.
Place of Meeting: Engineers and Architects Club of Louisville
Local Organization: Engineers and Architects Club
Number of Members: 50

Executive Committee

Ray Haselberger, *Chairman*
M. Sack, *Vice-Chairman*
L. L. Amidon, *Secretary*
W. L. Lucas, *Treasurer*
H. H. Fenwick
J. K. Meyer
J. A. Rabuck
J. H. Romann

MEMPHIS

Organized: 1923
Territory: Radius of sixty miles from Memphis, Tenn., and eastern half of Arkansas including all the territory east of a line drawn north and south through the western boundary of the city of Little Rock
Number of Members: 20

Executive Committee

M. D. Rust, *Chairman*
W. J. Fransioli, Jr., *Vice-Chairman*
R. B. H. Shepherd, *Secretary-Treasurer*
T. H. Allen
C. M. McCord
W. H. Roberts

METROPOLITAN

Organized: 1910
Territory: Metropolitan District, New York and New Jersey
Place of Meeting: Engineering Societies Building, 29 West 39th Street, New York, N.Y.
Number of Members: 3316

Executive Committee

T. B. Allardice, *Chairman*
E. H. Fezandie, *Secretary*
E. J. Billings, *Treasurer*

METROPOLITAN

(Continued)

F. D. CARVIN, *Chairman of Program Committee*
W. G. BLAKE
P. E. FRANK
W. McC. McKEE
A. R. MUMFORD
O. B. SCHIER, II
J. M. DRISCOLL, *Ex-Officio*

JUNIOR GROUP

SAM SHOOR, *Chairman*
C. K. HOLLAND, *Vice-Chairman*
A. E. BLIRER, *Secretary*
SIDNEY DAVIDSON
H. B. FERNALD, JR.
W. W. LAWRENCE
H. G. OLIVER, JR.
R. F. WARNER, JR.

MID-CONTINENT

Organized: 1919
Territory: Entire state of Oklahoma; territory in Arkansas not included in Memphis Section; part of Louisiana; and territory in Texas north of the southern boundaries of the counties of Gaines, Dawson, Bordon, Scurry, Fisher, Jones, and Shackelford
Place of Meeting: Usually Mayo Hotel, Tulsa, Okla.
Luncheon Meetings with Engineers Club of Tulsa, Mondays at 12:00 noon
Local Organization: Engineers Club of Tulsa
Number of Members: 142

EXECUTIVE COMMITTEE

H. R. AUERSWALD, *Chairman*
A. G. BLANCHARD, *Vice-Chairman*
L. C. PRICE, *Vice-Chairman*
G. RAYMOND, *Vice-Chairman*
HENRY SCHAEFER, *Vice-Chairman*
MAX WISE, *Secretary*
HERMAN WIENECKE, *Treasurer*
E. E. AMBROSIUS
R. G. AYERS
E. C. BAKER
W. L. DUCKER
W. G. HELTZEL
D. K. HUTCHCRAFT
A. J. KERR
H. T. SEARS
FRANK STIVERS

MILWAUKEE

Organized: 1909
Territory: Radius of fifty miles from Milwaukee, Wis.
Place of Meeting: Wisconsin Club
Local Organization: Engineers' Society of Milwaukee
Luncheon Meetings once each month, 3rd Wednesday at Wisconsin Club
Number of Members: 208

EXECUTIVE COMMITTEE

B. V. E. NORDBERG, *Chairman*
A. W. LINDSTROM, *Secretary-Treasurer*
W. D. BLISS
H. DAHLSTRAND
F. H. DORNER
A. H. LUEDICKE
W. C. LINDEMANN
R. C. NEWHOUSE
E. C. SCHUM
A. SIMON

JUNIOR GROUP

G. V. MINIBERGER, *Chairman*
R. H. MILLER, *Secretary*
GEORGE FRATCHER
RUSSELL HAHN
C. A. POFAHL, JR.
W. T. SAVELAND, JR.
ROBERT STRASSMAN

MINNESOTA

Organized: Minneapolis, 1913; St. Paul, 1913; the two Sections merged, 1934
Territory: Entire State of Minnesota
Place of Meeting: Minnesota Union, Univ. of Minnesota
Local Organization: Minneapolis Engineers' Club, Minnesota Federation of Architectural and Engineering Societies
Number of Members: 118

EXECUTIVE COMMITTEE

K. A. POWELL, *Chairman*
C. F. SHOOP, *Vice-Chairman*
L. G. STRAUB, *Secretary-Treasurer*
N. J. STERNAL
J. C. VANSELOW

NEBRASKA

Organized: 1922
Territory: State of Nebraska, and Council Bluffs, Iowa
Place of Meeting: Lincoln and Omaha
Local Organization: Engineers' Club of Lincoln and Omaha
Luncheon Meeting every Wednesday noon at the Omaha Engineers' Club—4th Monday Evening at Lincoln
Number of Members: 38

EXECUTIVE COMMITTEE

N. H. BERNARD, *Chairman*
A. A. LUEBS, *Vice-Chairman*
G. A. ROGERS, *Secretary-Treasurer*
J. W. BURNETT
J. H. COLSON
J. L. WHITE

NEW BRITAIN

Organized: 1921, as a Branch of Connecticut Section; reorganized as a Section, 1923
Territory: New Britain, Plainville, Forestville, Bristol, Kensington, and Berlin, Conn.
Place of Meeting: Auditorium of the State Trade School
Number of Members: 39

EXECUTIVE COMMITTEE

B. S. LEWIS, *Chairman*
C. N. FLAGG, *Vice-Chairman*
H. MICHELSEN, *Secretary-Treasurer*
P. W. BAUER
H. C. BARNES
H. RAMM
C. C. STEVENS
S. H. STONER

NEW HAVEN

Organized: 1912; reorganized, 1923
Territory: Portions of New Haven and Middlesex Counties, Conn.
Place of Meeting: Mason Laboratory, Yale University
Number of Members: 88

EXECUTIVE COMMITTEE

R. A. NORTH, *Chairman*
L. H. VON OHLSEN, *Secretary-Treasurer*
W. F. THOMPSON
A. L. BRECKENRIDGE
I. T. HOOK
W. L. TANN
F. J. COCHRAN

NEW ORLEANS

Organized: 1916
Territory: All of Louisiana except the northern part allotted to Mid-Continent Section
Place of Meeting: Room 422, St. Charles Hotel
Local Organization: Louisiana Engineering Society
Number of Members: 98

EXECUTIVE COMMITTEE

K. P. KAMMER, *Chairman*
L. J. LASSALLE, *Vice-Chairman*
G. R. HAMMETT, *Secretary-Treasurer*
C. A. BENDER
L. J. CUCULLU
J. S. HUEY
J. K. MAYER

JUNIOR GROUP

J. K. MAYER, *Chairman*
WALDEMAR NELSON, *Vice-Chairman*
R. B. JAMES, *Secretary*
E. A. MCLELLAN, *Treasurer*
J. R. ROMBACH, JR.
HENRY VOELKEL

NORTH TEXAS

Organized: 1922
Territory: Radius of one hundred and twenty-five miles from Dallas, in Texas
Place of Meeting: Dallas Power & Light Co. Bldg. Auditorium
Local Organization: Technical Club of Dallas
Number of Members: 93

EXECUTIVE COMMITTEE

N. G. HARDY, *Chairman*
C. A. COWLES, JR., *Vice-Chairman*
F. C. JUSTICE, *Secretary-Treasurer*
LEONARD COLE
C. L. KRIBS, JR.
R. M. MATSON
W. B. GREGORY, *Ex-Officio*

JUNIOR GROUP

J. K. CHATTEY, *Chairman*

NORWICH

Organized: 1930
Territory: Counties of Tolland, Windham, and New London in Connecticut, and Westerly District in Rhode Island

NORWICH

(Continued)

Place of Meeting: Arcanum Club, 150 Main St., Norwich
Number of Members: 39

EXECUTIVE COMMITTEE

E. S. DENNISON, *Chairman*
A. D. ANDRIOLA, *Secretary-Treasurer*
W. E. EDEL
F. S. ENGLISH
H. LEUHRS
A. E. WELCH
R. WOSAK

ONTARIO

Organized: 1917
Territory: Province of Ontario, Canada
Place of Meeting: Hart House, University of Toronto
Number of Members: 161

EXECUTIVE COMMITTEE

S. G. CLARKE, *Chairman*
G. E. ELLSWORTH, *Secretary-Treasurer*
O. H. ANDERSON
W. S. BALL
A. C. BLUE
D. F. CORNISH
C. R. DAVIS
F. G. EAST
R. B. ELLIOTT
W. G. MCINTOSH
W. E. MICKLETHWAITE
R. L. RUDE

JUNIOR GROUP

F. G. EAST, *Chairman*

OREGON

Organized: 1919
Territory: State of Oregon and that territory in Washington within a radius of thirty miles from Portland, Ore.
Place of Meeting: Usually Public Service Bldg., Portland, Ore.
Local Organization: Oregon Society of Engineers
Number of Members: 56

EXECUTIVE COMMITTEE

E. N. BATES, *Chairman*
R. B. ROWAN, *Vice-Chairman*
A. A. OSIPOVICH, *Secretary*
P. L. HESLOP
J. C. OTHUS
TOM PERRY

JUNIOR GROUP

H. JOHNSON, *Chairman*
W. E. CARSON, *Vice-Chairman*
R. R. STEINKE, *Secretary-Treasurer*

PENINSULA

Organized: 1923
Territory: West of the east boundaries of the following counties: Emmet, Charlevoix, Antrim, Kalkaska, Missaukee, Clare, Isabella, Gratiot, Clinton, Eaton, Calhoun, and Branch, Mich.
Place of Meeting: Grand Rapids, Mich.
Luncheon Meeting Fifth Thursday noon each month
Local Organization: Engineers' Club of Grand Rapids
Number of Members: 55

EXECUTIVE COMMITTEE

C. A. HAMILTON, *Chairman*
R. E. KLISE, *Secretary-Treasurer*
C. G. LOHMANN
E. E. NORMAN
B. E. PORTER

PHILADELPHIA

Organized: 1912
Territory: Counties of Bucks, Montgomery, Chester, Philadelphia, Delaware, Pa., and the State of Delaware
Place of Meeting: Philadelphia Engineers' Club, 1317 Spruce Street, Philadelphia, Pa.
Local Organization: Philadelphia Engineers' Club
Luncheon Meeting every Thursday noon at 12:30 p.m. at Philadelphia Engineers' Club
Number of Members: 849

EXECUTIVE COMMITTEE

E. L. HOPPING, *Chairman*
L. P. HYNES, *Vice-Chairman*
J. S. MOREHOUSE, *Secretary-Treasurer*
C. S. GOTWALS
L. N. GULICK
C. C. JONES

JUNIOR GROUP

J. P. CLARK, *Chairman*
T. M. POMEROY, JR., *Vice-Chairman*
J. D. PETERSON, *Secretary*
G. K. FISHER, *Treasurer*
E. W. GRISCOM
R. K. KNIPE
W. B. PEGRAM
Z. T. WOBENSMITH, 2ND

PITTSBURGH

Organized: 1920
Territory: Counties bounded by and including Beaver, Butler, Venango, Forest, Jefferson, Indiana, Somerset, Fayette, Greene, and Washington, Pa.
Place of Meeting: Engineers' Society of Western Pennsylvania, William Penn Hotel
Local Organization: Engineers' Society of Western Pennsylvania
Number of Members: 424

EXECUTIVE COMMITTEE

W. D. CANAN, *Chairman*
M. R. MCCONNEL, *Secretary*
K. F. TRESCHOW, *Treasurer*
A. BUTCHER
B. C. MCFADDEN
T. E. PURCELL

PLAINFIELD

Organized: 1921
Territory: Plainfield and territory included between Elizabeth, Bound Brook, Metuchen, and Watchung, N.J.
Place of Meeting: Elizabeth Carteret Hotel, Elizabeth, and Plainfield Masonic Temple, Plainfield
Local Organization: Plainfield Engineers Club, Singer Engineering Society
Number of Members: 192

EXECUTIVE COMMITTEE

D. V. WATERS, *Chairman*
G. E. LEAVITT, JR., *Vice-Chairman*
F. C. SPENCER, JR., *Secretary*
C. G. HOLMBERG, JR., *Treasurer*
R. S. AUSTIN
F. C. FROLANDER
JOHN HAYDOCK
JOSEPH KERR

PROVIDENCE

Organized: 1920
Territory: Radius of thirty miles from Providence, R.I.
Place of Meeting: Providence Engineering Society Building, 195 Angell St., Providence, R.I.
Local Organization: Providence Engineering Society
Number of Members: 156

EXECUTIVE COMMITTEE

H. S. SIZER, *Chairman*
A. W. CALDER, JR., *Vice-Chairman*
R. M. SCOTT, *Secretary-Treasurer*
F. S. BLACKALL, JR.
J. D. ELDERT
J. E. ENGLUND
E. W. FREEMAN
N. D. MACLEOD
S. A. VAULE
R. L. WALES

RALEIGH

Organized: As a Branch, 1923; as a Section, 1927
Territory: Radius of sixty miles from Raleigh, N.C.
Place of Meeting: N.C. State College, Raleigh, N.C.
Local Organization: N.C. Engineering Council, Raleigh Engineers Club
Number of Members: 36

EXECUTIVE COMMITTEE

R. S. WILBUR, *Chairman*
C. E. KERCHNER, *Vice-Chairman*
C. N. SANFORD, *Secretary-Treasurer*
F. F. GROSECLOSE
E. G. HOEFER
F. J. REED

ROCHESTER

Organized: 1919
Territory: Radius of thirty miles from Rochester, N.Y.
Place of Meeting: Rochester Engineering Society Rooms, Sagamore Hotel
Local Organization: Rochester Engineering Society, Sagamore Hotel
Luncheon Meeting every Tuesday at 12:15 p.m. at Sagamore Hotel
Number of Members: 108

ROCHESTER

(Continued)

EXECUTIVE COMMITTEE

J. H. SNYDER, *Chairman*
I. S. BRADLEY, *Vice-Chairman*
I. G. MCCHESNEY, *Secretary-Treasurer*
J. W. GAVETT
K. H. HUBBARD
H. F. KURTZ
P. B. WESSON

ROCK RIVER VALLEY

Organized: 1926
Territory: Radius of thirty miles from Rockford, Ill., plus members in Madison, Wis.
Meeting Place: Place varies
Local Organization: Rockford Engineering Society
Number of Members: 61

EXECUTIVE COMMITTEE

G. L. LARSON, *Chairman*
C. L. AVERY, *Vice-Chairman*
L. A. WILSON, *Secretary*
B. G. ELLIOTT
R. C. GLAZEBROOK
W. C. VON FISCHER
C. KRAUS, *Junior Member*

ST. JOSEPH VALLEY

Organized: 1929
Territory: Counties of La Porte, Starke, Pulaski, St. Joseph, Marshall, Fulton, Elkhart, and Kosciusko in Indiana, and Cass and Berrien Counties in Michigan
Place of Meeting: Morningside Hotel, South Bend, Ind.
Local Organization: St. Joseph Valley Engineers' Club
Number of Members: 36

EXECUTIVE COMMITTEE

C. C. WILCOX, *Chairman*
C. R. ADAMS, *Vice-Chairman*
K. W. KNORR, *Secretary-Treasurer*

ST. LOUIS

Organized: 1909
Territory: Radius of thirty miles from St. Louis, Mo.
Place of Meeting: Place varies
Local Organization: Engineers' Club of St. Louis
Number of Members: 208

EXECUTIVE COMMITTEE

D. E. DICKEY, *Chairman*
ALBERT VIGNE, *Vice-Chairman*
C. B. BRISCOE, *Secretary-Treasurer*
C. J. COLLEY
A. L. HEINTZE
R. W. MERKLE

SAN FRANCISCO

Organized: 1910
Territory: All territory north of the northern boundaries of the counties of San Luis Obispo, Kern, and San Bernardino
Place of Meeting: Engineers' Club, 206 Sansome St.
Luncheon Meetings, Tuesdays, California Hotel, Oakland; Thursdays, Engineers' Club, San Francisco
Local Organization: San Francisco Engineers' Club
Number of Members: 385

EXECUTIVE COMMITTEE

G. H. RAITT, *Chairman*
V. F. ESTCOURT, *Vice-Chairman*
H. B. LANGILLE, *Secretary-Treasurer*
WARREN DOBLE, *Corresponding Secretary*
K. B. ANDERSON
W. HARRY ARCHER
H. T. AVERY
R. B. PLASS
G. N. SOMERVILLE

JUNIOR GROUP

G. GALE SULLIVAN, *Chairman*
W. M. BRASHEAR, *Secretary*
BERT HIRSCH
J. W. R. LEMERY
BERT TRUETT
J. E. ZORN

SAVANNAH

Organized: 1923
Territory: Radius of 125 miles from Savannah in Georgia
Place of Meeting: Savannah Hotel
Local Organization: Engineers' Council of Savannah Chamber of Commerce
Number of Members: 21

EXECUTIVE COMMITTEE

A. P. KEISKER, *Chairman*
W. R. BROWN, *Secretary*
ALEX. M. ORMOND
LOUIS ROESEL
BRUCE SAMS

SCHENECTADY

Organized: As a Branch, 1919; as a Section, 1927
Territory: Radius of thirty miles from Schenectady, N.Y.
Place of Meeting: Rice Hall
Number of Members: 172

EXECUTIVE COMMITTEE

A. L. RUIZ, *Chairman*
S. L. JAMESON, *Vice-Chairman*
E. E. PARKER, *Vice-Chairman*
A. R. STEVENSON, JR., *Vice-Chairman*
R. H. NORRIS, *Secretary*
CARL SCHABTACH, *Treasurer*
J. L. FLETCHER
H. M. OTTO
O. L. WOOD, JR.

SOUTH TEXAS

Organized: 1919
Territory: South Texas and the northern part of the State not included in the North Texas Section territory
Place of Meeting: Electric Bldg., Houston, Tex.
Number of Members: 171

EXECUTIVE COMMITTEE

J. J. KING, *Chairman*
C. W. CRAWFORD, *Vice-Chairman*
H. F. MOLLER, *Secretary-Treasurer*
HERBERT ALLEN
D. D. ALTON
J. W. BERETTA
A. H. BURR
H. E. DEGLER
JOHN DOGGETT, JR.
H. G. HIEBELER
F. M. LEVERETT
J. S. NETHERWOOD
C. L. ORR

SUSQUEHANNA

Organized: 1927
Territory: Counties of Cumberland, Dauphine, Lebanon, Adams, York, and Lancaster
Place of Meeting: Engineering Society of York, and at Lancaster Twice a Year
Local Organization: Engineering Society of York and Engineers' Society of Pennsylvania, Harrisburg, Pa.
Number of Members: 79

EXECUTIVE COMMITTEE

W. E. BELINE, *Chairman*
O. E. WEBER, *Vice-Chairman*
E. T. P. NEUBAUER, *Secretary*
E. E. AUGHENBAUCH
T. K. BREDA
M. G. LEESON
H. B. MARTIN
W. NOYES
GERALD SMITH
S. P. SOLING

SYRACUSE

Organized: 1920
Territory: Radius of thirty miles from Syracuse, N.Y.
Place of meeting: Ball Room of the Onondaga Hotel
Local Organization: The Technology Club of Syracuse
Number of Members: 81

EXECUTIVE COMMITTEE

MORRIS F. WILLIAMS, *Chairman*
R. C. PAUL, *Vice-Chairman*
E. KEITH RHODES, *Secretary-Treasurer*
H. B. CRAIG
C. F. DIETZ
E. A. FAILMEZGER
W. F. JONES

TOLEDO

Organized: 1920
Territory: Radius of thirty miles from Toledo, Ohio
Place of Meeting: University Club, Toledo, Ohio
Local Organization: Affiliated Technical Societies of Toledo
Number of Members: 62

EXECUTIVE COMMITTEE

R. F. HILL, *Chairman*
H. O. KRANICH, *Vice-Chairman*

TOLEDO

(Continued)

N. R. Ohler, *Secretary-Treasurer*
C. A. Alexander
J. W. Dean
Carl Frautschi
John Gillett
H. E. Happel
R. J. Mugfor
D. M. Palmer
W. Schroeder
H. R. Schultz
H. H. Vogel
E. W. Weaver
I. F. Zarobsky

TRI-CITIES

Organized: 1920
Territory: Radius of thirty miles from Moline, Ill.
Place of Meeting: Rock Island, Ill., Moline, Ill., and Davenport, Iowa
Luncheon Meeting every Wednesday, Davenport Hotel, 12:00 noon
Number of Members: 61

Executive Committee

R. A. Cross, *Chairman*
H. A. Kleinman, *Vice-Chairman*
C. A. Carlson, *Secretary-Treasurer*
P. E. Anderson
R. M. Barnes
J. M. Hartman

UTAH

Organized: 1923
Territory: State of Utah
Place of Meeting: University Club, Salt Lake City
Local Organization: Utah Society of Engineers
Number of Members: 40

Executive Committee

H. M. Ferguson, *Chairman*
W. D. Turpin, *Vice-Chairman*
G. M. Jones, *Secretary*
R. D. Baker
W. H. Trask, Jr.

VIRGINIA

Organized: 1919
Territory: State of Virginia
Place of Meeting: Richmond, Norfolk, Charlottesville, Roanoke, University, Petersburg
Local Organization: Central Virginia Engineers Club
Number of Members: 142

Executive Committee

G. L. Bascome, *Chairman*
G. C. Molleson, *Vice-Chairman*
J. B. Jones, *Secretary*
F. S. Roop, Jr., *Treasurer*
E. B. Boynton
D. F. Evans
L. R. Gardner
D. G. Moorhead
W. E. Segl

WASHINGTON, D.C.

Organized: 1919
Territory: District of Columbia
Place of Meeting: Auditorium, Potomac Electric Power Co., 10th & E Sts., Washington, D.C.
Number of Members: 234

Executive Committee

H. G. Thielscher, *Chairman*
G. F. Jenks, *Vice-Chairman*
C. E. Miller, *Secretary-Treasurer*
A. T. Dupont
W. B. Ensinger
A. F. Johnson
Paul Weeks

WATERBURY

Organized: 1917, as a Branch; reorganized as a Section, 1923
Territory: Litchfield County and a portion of New Haven County
Place of Meeting: Elton Hotel
Number of Members: 73

Executive Committee

W. C. Schneider, *Chairman*
L. J. Niekirk, *Vice-Chairman*
R. B. Bass, *Secretary-Treasurer*
C. W. Childs
A. J. German
R. C. Perry

Junior Group

W. B. McKenzie, Jr., *Chairman*
R. W. Simpson, Jr., *Secretary-Treasurer*
H. C. Ashley
G. N. Tyack

WESTERN MASSACHUSETTS

Organized: 1922
Territory: Includes counties of Berkshire, Franklin, Hampden, and Hampshire
Place of Meeting: Highland Hotel, Springfield, Mass.
Local Organization: Engineering Society of Western Massachusetts
Number of Members: 87

Executive Committee

J. L. Scherner, *Chairman*
A. H. Lewis, *Vice-Chairman*
L. G. Carlton, *Secretary-Treasurer*
A. E. Benson
Lester Campbell
F. R. Shoemaker

WESTERN WASHINGTON

Organized: 1919
Territory: State of Washington west of Columbia River with exception of territory included in 30-mile radius of Portland, Ore.
Place of Meeting: Engineers' Club, Seattle, Wash.
Local Organization: Seattle Engineers' Club
Luncheon Meetings daily at noon at Engineers' Club, Seattle
Number of Members: 101

Executive Committee

H. J. McIntyre, *Chairman*
Eddy Floodeen, *Vice-Chairman*
R. E. Walter, *Secretary-Treasurer*
H. L. Adams
H. P. Ford
B. T. McMinn
C. J. Yost

WEST VIRGINIA

Organized: 1925
Territory: State of West Virginia, South of Parallel 39
Place of Meeting: Charleston, W.Va.
Number of Members: 60

Executive Committee

C. L. Johnson, *Chairman*
M. S. Bloomsburg, *Vice-Chairman*
H. B. Hickman, *Secretary-Treasurer*
B. B. Betty
H. L. Carspecken, Jr.
E. L. Hudson
F. LeRoy Schaefer
H. C. Skaggs, Jr.

WORCESTER

Organized: 1915
Territory: Radius of thirty miles from Worcester, Mass.
Place of Meeting: Sanford Riley Hall, Worcester Poly. Inst.
Local Organization: Worcester Engineering Society
Number of Members: 125

Executive Committee

F. R. Jones, *Chairman*
R. P. Kolb, *Vice-Chairman*
R. H. Wood, *Secretary-Treasurer*
E. K. Allen, Jr.
E. N. Armstrong
H. P. Crane
R. F. Gow
C. M. McMahon
Otto Muller
E. H. Smith

Junior Group

W. M. Wilcox, *Chairman*
Wilfred Ogg, *Vice-Chairman*
W. H. Davenport, *Secretary-Treasurer*
W. F. Beth
J. E. Guild
Thos. Hill
Geo. Palmenter
Irwin Peterson
W. S. Snow
N. G. Stradtherr

YOUNGSTOWN

Organized: 1928
Territory: Counties of Trumbull, Mahoning, and Columbiana in Ohio, and Mercer and Lawrence in Pennsylvania
Place of Meeting: Republic Rubber Co. Club Rooms, Albert St., Youngstown, Ohio
Number of Members: 58

Executive Committee

H. W. Smith, *Chairman*
L. A. Kline, *Vice-Chairman*
C. W. Foard, *Secretary-Treasurer*
F. J. Bowers
W. B. Jenkins
H. E. Melin
E. O. Oyen

STUDENT BRANCHES

ARTICLE B6A, PAR. 20: The Standing Committee on Relations With Colleges shall, under the direction of the Council, have supervision of the Student Branches of the Society and of such work of the Society as aims to further the education of engineers through the colleges and schools of accepted standing.

STANDING COMMITTEE, RELATIONS WITH COLLEGES

H. O. CROFT, *Chairman* (1940)
E. W. O'BRIEN (1941)
A. C. CHICK (1942)
J. D. CUNNINGHAM (1943)
P. B. EATON (1944)

H. E. DEGLER
S. F. DUNCAN
E. O. EASTWOOD
F. H. PROUTY
G. L. SULLIVAN
Advisory Members (1940)

J. I. YELLOTT, *Junior Adviser* (1940)

Communicate with Student Branch through Honorary Chairman

RESEARCH TECHNICAL COMMITTEES

ARTICLE B6A, PAR. 24: The Standing Committee on Research shall advise the Council on the research work of the Society.

The first Standing Committee on Research was organized in 1909.

STANDING COMMITTEE

L. W. WALLACE, *Chairman* (1940)
E. G. BAILEY (1941)
W. TRINKS (1942)
M. D. HERSEY (1943)
J. H. WALKER (1944)

LUBRICATION

Appointed October, 1915, to investigate the fundamental problems of lubrication, to formulate results of investigations previously made, and to keep in touch with contemporary research in this field

(Reorganized May, 1936)

G. B. KARELITZ, *Chairman*
S. J. NEEDS, *Secretary*
A. L. BEALL
OSCAR BRIDGEMAN
W. E. CAMPBELL
H. P. DAHLSTRAND
H. A. EVERETT
A. E. FLOWERS
J. C. GENIESSE
RAYMOND HASKELL
M. D. HERSEY
B. F. HUNTER
C. M. LARSON
F. C. LINN
G. L. NEELY
B. L. NEWKIRK
A. E. NORTON
E. S. PEARCE
ERNEST WOOLER

FLUID METERS

Appointed 1916 to develop the theory of fluid meters of all kinds and to report on the best methods for their installation and use

(Reorganized July, 1926)

R. J. S. PIGOTT, *Chairman*
J. R. CARLTON, *Secretary*
H. S. BEAN
S. R. BEITLER
E. O. BENNETT
R. K. BLANCHARD
B. O. BUCKLAND
LOUIS GESS
A. J. KERR
T. H. KERR
M. P. O'BRIEN
W. S. PARDOE
L. K. SPINK
R. E. SPRENKLE
E. C. M. STAHL
T. R. WEYMOUTH
M. J. ZUCROW

THERMAL PROPERTIES OF STEAM

Appointed in December, 1921, to direct research on the thermal properties of water-vapor and steam from 0 C to the upper limits of temperature and pressure

(Reorganized April, 1929)

W. L. ABBOTT, *Vice-Chairman*
H. N. DAVIS
H. C. DICKINSON
A. M. GREENE, JR.
R. C. H. HECK
D. S. JACOBUS
MAX JAKOB
J. H. KEENAN
F. G. KEYES
L. S. MARKS
G. A. ORROK
R. J. S. PIGOTT
H. V. RASMUSSEN
E. L. ROBINSON

STRENGTH OF GEAR TEETH

Appointed in December, 1921. Is investigating factors affecting the strength and life of gear teeth

R. E. FLANDERS, *Chairman*
C. H. LOGUE, *Secretary*
C. G. BARTH
EARLE BUCKINGHAM
A. M. GREENE, JR.
C. W. HAM
F. E. MCMULLEN
E. W. MILLER
ERNEST WILDHABER

CUTTING OF METALS

Appointed in September, 1923. Is studying the problems of metal cutting, including tool materials, tool design, lubrication, cooling, and speeds and fuels

M. F. JUDKINS, *Chairman*
L. N. GULICK, *Secretary*
L. P. ALFORD
O. W. BOSTON
R. C. DEALE
A. L. DELEEUW
C. M. THOMPSON, JR.

MECHANICAL SPRINGS

Appointed May, 1924, to determine the status of the mechanical-spring art, to promote and conduct necessary and adequate research, and to develop the art to the point of standardization

J. R. TOWNSEND, *Chairman*
C. T. EDGERTON, *Secretary*
C. E. BARBA
W. G. BROMBACHER
R. W. COOK
W. T. DONKIN
RUPEN EKSERGIAN
G. E. HANSEN
BENJAMIN LIEBOWITZ
DAVID LOFTS
(R. D. BRIZZOLARA, *Alternate*)
D. J. MCADAM, JR.
R. E. PETERSON
J. B. REYNOLDS
J. W. ROCKEFELLER, JR.
B. W. ST. CLAIR
M. F. SAYRE
T. R. WEBER
KEITH WILLIAMS
J. K. WOOD
F. P. ZIMMERLI
O. B. ZIMMERMAN

ELEVATORS

Appointed June, 1924, as a subcommittee of the Sectional Committee on Safety Code for Elevators, to study the function and operation of elevator safeties and buffers and their associated mechanisms and to develop methods of test for the approval of elevator safety devices

D. J. PURINTON, *Chairman*
O. P. CUMMINGS, *Vice-Chairman*
J. A. DICKINSON, *Secretary*
BASSETT JONES
D. L. LINDQUIST
M. G. LLOYD
J. J. MATSON
M. B. MCLAUTHLIN
W. S. PAINE

EFFECT OF TEMPERATURE ON THE PROPERTIES OF METALS

Appointed December, 1924, as a joint research committee of the A.S.T.M. and the A.S.M.E. to encourage the investigation and accumulation of data on the properties of metals used in the mechanic arts at extremely high and low temperatures

N. L. MOCHEL, *Chairman*
H. J. KERR, *Vice-Chairman*
J. W. BOLTON, *Secretary*
R. H. ABORN
W. H. ARMACOST
A. B. BAGSAR
A. D. BAILEY
F. E. BASH
E. S. DIXON
F. B. FOLEY
J. R. FREEMAN, JR.
H. J. FRENCH
H. W. GILLETT
A. J. HERZIG
G. F. JENKS
J. J. KANTER
C. E. MACQUIGG
P. E. MCKINNEY
E. L. ROBINSON
A. E. WHITE
Director, National Bureau of Standards, U.S. Department of Commerce
Representative of Bureau of Engineering, U.S. Navy Department

BOILER FEEDWATER STUDIES

Appointed March, 1925, as a Joint Research Committee of the American Boiler Manufacturers Association, American Railway Engineering Association, American Water Works Association, Edison Electric Institute, the American Society for Testing Materials, and the A.S.M.E. to study methods of analysis and treatment of boiler feedwater for stationary and railroad practice

BOILER FEEDWATER STUDIES

(Continued)

EXECUTIVE COMMITTEE (Total personnel 41)

C. H. FELLOWS, *Chairman*
R. C. BARDWELL, *Vice-Chairman*
J. B. ROMER, *Secretary*
A. G. CHRISTIE *
R. E. COUGHLIN
B. W. DE GEER
MAX HECHT
H. E. JORDAN
W. F. KEENAN, JR.
P. B. PLACE
S. T. POWELL
F. N. SPELLER
M. F. STACK
E. H. TENNEY
A. E. WHITE *

CONDENSER TUBES

Appointed May, 1925, to investigate and report on the causes of failure of tubes used in steam condensers and similar heat interchange apparatus

A. E. WHITE, *Chairman*
D. C. WEEKS, *Vice-Chairman*
P. A. BANCELL
D. K. CRAMPTON
H. M. CUSHING
R. E. DILLON
O. B. J. FRASER
J. R. FREEMAN, JR.
V. M. FROST
C. F. HARWOOD
G. C. HOLDER
O. Z. KLOPSCH
H. W. LEITCH
E. F. MILLER
W. B. PRICE
M. F. STACK
H. A. STAPLES
W. R. WEBSTER
Director, Bureau of Engineering, U.S. Navy Department

BOILER FURNACE REFRACTORIES

Appointed June, 1925, to determine the principal factors governing the failure of refractories in various types of installations, to subject these factors to detailed experimental analysis, to undertake the formulation of suitability tests and, if necessary, to attempt to develop a suitable refractory to meet the needs of severe service

W. A. CARTER, *Chairman*
S. H. BARNUM
G. A. BOLE
M. C. BOOZE
W. H. FULWEILER
C. B. GRADY
R. A. HEINDL
R. K. HURSH
N. E. LEWIS
J. S. McDOWELL
(F. A. HARVEY, *Alternate*)
S. J. McDOWELL
PERCY NICHOLLS
S. M. PHELPS
E. B. POWELL
R. A. SHERMAN
R. B. SOSMAN
L. J. TROSTEL
G. B. WILKES

* Official A.S.M.E. representatives serving on this committee.

WORM GEARS

Appointed May, 1927, to investigate certain problems in connection with the action of worm gear drives and to recommend improvements in their design, manufacture, and use

EARLE BUCKINGHAM, *Chairman*
G. H. ACKER
L. R. BUCKENDALE
W. H. HIMES
D. L. LINDQUIST
A. A. ROSS
B. F. WATERMAN
Representative of Bureau of Engineering, U.S. Navy Department

MEASURES OF MANAGEMENT

Appointed March, 1928, to attempt the reconciliation of certain economic laws affecting production, to develop formulas for management, and to collect and report information on management research

W. E. FREELAND, *Chairman*
F. E. RAYMOND, *Secretary*
J. H. BARBER
T. H. BROWN
R. C. DAVIS
G. E. HAGEMANN

ABSORPTION OF RADIANT HEAT IN BOILER FURNACES

Appointed April, 1928, to make a study of the absorption of radiant heat in boiler furnaces with the purpose of developing recommendations on improved furnace design

W. J. WOHLENBERG, *Chairman*
E. G. BAILEY
R. M. GATES
C. W. GORDON
E. L. LINDSETH
G. A. ORROK
R. J. S. PIGOTT
JOHN VAN BRUNT

STRENGTH OF VESSELS UNDER EXTERNAL PRESSURE

Appointed June, 1929, to develop reliable design data on the strength of cylindrical and spherical surfaces under external pressure, particularly with reference to jacketed vessels

W. D. HALSEY, *Chairman*
F. V. HARTMAN
M. B. HIGGINS
A. W. LIMONT, JR.
H. E. SAUNDERS
E. E. SHANOR
D. B. WESSTROM
F. S. G. WILLIAMS
D. F. WINDENBURG

WIRE ROPE

Appointed April, 1930, to investigate existing rope so that it may be better understood and more effectively used

W. H. FULWEILER, *Chairman*
H. LeR. BRINK
D. L. LINDQUIST
G. W. MARTIN
C. A. McCUNE
A. H. McDOUGALL
B. V. E. NORDBERG, JR.
W. S. PAINE
W. J. RYAN
GEORGE SIMPSON
L. E. YOUNG

CRITICAL PRESSURE STEAM BOILERS

Appointed June, 1931, to study the characteristics of high-pressure forced-circulation steam-generating units

H. L. SOLBERG, *Chairman*
W. H. ARMACOST
A. D. BAILEY
E. G. BAILEY
F. S. CLARK
C. H. FELLOWS
H. J. KERR
M. W. LINK
G. A. ORROK
E. L. ROBINSON
P. W. THOMPSON

COTTONSEED PROCESSING

Appointed December, 1932, to study the mechanical problems involved in storing, conditioning, and cooking cottonseed meats

W. R. WOOLRICH, *Chairman*
HOMER BARNES
E. L. CARPENTER
C. E. GARNER
B. J. SAMS
R. B. TAYLOR

ROLLING OF STEEL (PLASTICITY)

Appointed October, 1938, to study plasticity in the particular field of rolling of steel

W. TRINKS, *Chairman*
E. C. BAIN
C. L. EKSERGIAN
J. H. HITCHCOCK
G. B. KARELITZ
C. W. MacGREGOR
A. NADAI
MORRIS STONE

A.S.M.E. Representatives on Other Research Committees

See also A.S.M.E. Representatives on Other Activities, page RI-5

AMERICAN COORDINATING COMMITTEE ON CORROSION

American Society for Testing Materials

S. L. KERR
(C. H. FELLOWS, *Alternate*)

CORROSION COMMITTEE

American Society of Refrigerating Engineers

(To be appointed)

FATIGUE PHENOMENA OF METALS

American Society for Testing Materials

C. T. EDGERTON

HEAT-TREATMENT OF ROCK DRILL STEELS

Advisory Board of the National Bureau of Standards and Bureau of Mines

(To be appointed)

METALLURGICAL RESEARCH

Advisory Committee to the National Bureau of Standards

C. H. BIERBAUM

PROPERTIES OF REFRACTORY MATERIALS

Advisory Committee to the National Bureau of Standards

E. B. POWELL

WATER FOR INDUSTRIAL USES

American Society for Testing Materials

J. H. WALKER

STANDARDIZATION TECHNICAL COMMITTEES

ARTICLE B6A, PAR. 23: The Standing Committee on Standardization shall advise the Council on the dimensional standardization work of the Society, including relations with the American Standards Association.

The first Standing Committee on Standardization was organized in April, 1911.

STANDING COMMITTEE

W. C. MUELLER, *Chairman* (1940)
A. L. BAKER (1941)
J. E. LOVELY (1942)
J. R. WEAVER (1943)
T. E. FRENCH (1944)

STANDARDIZATION AND UNIFICATION OF SCREW THREADS (B1)

* *Joint sponsorship with the Society of Automotive Engineers. Sectional Committee originally organized in June, 1921. Reorganized in February, 1929*

A.S.M.E. Members (Total personnel, 35)

R. E. FLANDERS, *Chairman* †
EARLE BUCKINGHAM, *Secretary*
E. J. BRYANT
G. S. CASE
T. G. CRAWFORD
A. M. HOUSER †
H. C. E. MEYER
P. V. MILLER †
W. C. MUELLER
R. H. PERRY
O. B. ZIMMERMAN

SUBCOMMITTEE CHAIRMEN

No. 1 on Scope, Arrangement, and Editing of American National Standard, R. E. FLANDERS
No. 2 on Terminology and Thread Specifications, Except Gages, C. W. BETTCHER
No. 3 on Special Threads and Twelve Pitch Series, Except Gages
No. 4 on Acme and Other Similar Threads, Except Gages, EARLE BUCKINGHAM
No. 5 on Screw Thread Gages and Inspection, G. S. CASE
No. 7 on Wood Screws, ARTHUR BOOR

Special Subcommittee on Revision of American Standard, P. V. MILLER

* Note: All of these standards committees for which the Society is sponsor or joint sponsor, or on which it has representation, are organized under the procedure of the American Standards Association.

† Official A.S.M.E. representative serving on this committee.

PIPE THREADS (B2)

* *Joint sponsorship with the American Gas Association. Sectional Committee originally organized in 1913. Reorganized May, 1927*

A.S.M.E. Members (Total personnel, 46)

A. S. MILLER, *Chairman*
C. B. LEPAGE, *Acting Secretary*
A. F. BREITENSTEIN
E. J. BRYANT
C. S. COLE
E. S. CORNELL, JR.
J. J. CROTTY
A. P. DENTON
J. J. HARMAN
A. M. HOUSER †
A. H. JARECKI
P. V. MILLER
F. H. MOREHEAD
W. C. MORRIS
S. F. NEWMAN
L. N. SHANNON
W. D. SIZER
J. H. WILLIAMS

SUBCOMMITTEE CHAIRMEN

No. 1 on Editing and Gaging, A. M. HOUSER
No. 2 on Taper Pipe Threads, S. B. TERRY
No. 3 on Straight Pipe Threads, A. S. MILLER
No. 4 on Plumbers' Threads, A. F. BREITENSTEIN
No. 5 on Screw Threads for Rigid Steel Conduit, JAMES BARTON
No. 6 on Special Threads for Thin Tubes, C. C. WINTER

Special Subcommittee on Truncation, E. J. BRYANT

BALL AND ROLLER BEARINGS (B3)

* *Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized December, 1920*

A.S.M.E. Members (Total personnel, 14)

W. P. KENNEDY, *Vice-Chairman* †
D. E. BATESOLE †
L. A. CUMMINGS
F. G. HUGHES
G. E. HULSE †
L. F. NENNINGER
ERNEST WOOLER

ALLOWANCES AND TOLERANCES FOR CYLINDRICAL PARTS AND LIMIT GAGES (B4)

* *Sole sponsorship. Sectional Committee originally organized in June, 1920. Reorganized in September, 1930*

A.S.M.E. Members (Total personnel, 43)

J. E. LOVELY, *Chairman* †
F. E. BANFIELD, JR.
F. S. BLACKALL, JR.
E. J. BRYANT
EARLE BUCKINGHAM †
F. H. COLVIN †
T. G. CRAWFORD
R. E. W. HARRISON
F. O. HOAGLAND
N. E. JACOBI
H. C. E. MEYER
P. V. MILLER
W. C. MUELLER
E. C. PECK †
R. H. PERRY
W. C. SCHOENFELDT
C. C. STEVENS
O. B. ZIMMERMAN

SUBCOMMITTEE CHAIRMAN

No. 1 on Tolerance Systems, R. E. W. HARRISON

SMALL TOOLS AND MACHINE TOOL ELEMENTS (B5)

* *Joint sponsorship with the National Machine Tool Builders Association and the Society of Automotive Engineers. Sectional Committee organized September, 1922*

A.S.M.E. Members (Total personnel, 25)

W. C. MUELLER, *Chairman* †
F. O. HOAGLAND, *Vice-Chairman*
J. B. ARMITAGE
O. W. BOSTON
E. J. BRYANT
EARLE BUCKINGHAM
F. H. COLVIN †
S. A. EINSTEIN
H. E. HARRIS †
JOHN HAYDOCK
J. P. LAUX †
J. E. LOVELY
ERIK OBERG

SMALL TOOLS AND MACHINE TOOL ELEMENTS (*Continued*)

TECHNICAL COMMITTEES

No. 1 ON T-SLOTS

A.S.M.E. Members (Total personnel, 7)

ERIK OBERG, *Chairman* †
J. B. ARMITAGE
HARRY CADWALLADER, JR.†
S. A. EINSTEIN
F. O. HOAGLAND †

No. 2 ON TOOL POSTS AND TOOL SHANKS

A.S.M.E. Members (Total personnel, 8)

O. W. BOSTON, *Chairman*
F. S. BLACKALL, JR.
GRANGER DAVENPORT †
M. E. LANGE

No. 3 ON MACHINE TAPERS

A.S.M.E. Members (Total personnel, 20)

E. J. BRYANT, *Chairman* †
C. B. LEPAGE, *Acting Secretary*
J. B. ARMITAGE
F. S. BLACKALL, JR.
EARLE BUCKINGHAM †
F. H. COLVIN
J. B. DILLARD
(T. F. GITHENS, *Alternate*)
B. P. GRAVES
H. E. HARRIS
F. O. HOAGLAND †
J. H. HORIGAN
A. H. LYON
L. F. NENNINGER

SUBGROUP CHAIRMEN

Steep Tapers Series, S. MCMULLAN
Revision of Slow Taper Standard, E. J. BRYANT

No. 4 ON SPINDLE NOSES AND COLLETS FOR MACHINE TOOLS

A.S.M.E. Members (Total personnel, 26)

J. E. LOVELY, *Chairman* †
L. F. NENNINGER, *Secretary*
J. B. ARMITAGE
B. P. GRAVES
F. O. HOAGLAND †
A. M. JOHNSON
M. E. LANGE
J. H. MANSFIELD
L. D. SPENCE

SUBGROUP CHAIRMEN

No. 1 on Milling Machines, Small and Medium, J. B. ARMITAGE
No. 2 on Large Milling Machines, F. B. KAMPMEIER
No. 3 on Grinding Machine Spindles, H. J. GRIFFING
No. 5 on Drilling Machines and Horizontal Boring Machines, S. MCMULLAN
No. 6 on Turning Machines, Including Automatic Screw Machines, Lathes, Automatic Lathes, Turret Lathes, and Automatic Chucking Machines, J. E. LOVELY
No. 8 on Correlation of Counter Proposals for Spindle Noses, J. E. LOVELY

No. 5 ON MILLING CUTTERS

A.S.M.E. Members (Total personnel, 20)

J. B. ARMITAGE
A. N. GODDARD †
J. H. HORIGAN
G. L. MARKLAND, JR.
E. K. MORGAN
ERIK OBERG †
E. D. VANCIL

SUBGROUP CHAIRMEN

No. 1 on Profile Cutters, E. D. VANCIL
No. 2 on Keyways, J. B. ARMITAGE
No. 3 on Nomenclature, A. C. DANEKIND
No. 4 on Limits, J. H. HORIGAN
No. 5 on Formed Cutters, H. C. HUNGERFORD
No. 6 on Hobs, G. L. MARKLAND, JR.
No. 7 on Inserted Tooth Cutters, J. B. ARMITAGE

No. 6 ON DESIGNATIONS AND WORKING RANGES OF MACHINE TOOLS

A.S.M.E. Members (Total personnel, 19)

JOHN HAYDOCK, *Chairman*
EARLE BUCKINGHAM †
T. H. DOAN, JR.
B. P. GRAVES †
J. J. MCBRIDE
E. R. SMITH

No. 7 ON TWIST DRILL SIZES

A.S.M.E. Members (Total personnel, 7)

W. C. MUELLER, *Chairman* †
J. H. HORIGAN †

No. 8 ON JIG BUSHINGS

A.S.M.E. Member (Total personnel, 8)

J. H. HORIGAN †

No. 9 ON PUNCH PRESS TOOLS

A.S.M.E. Members (Total personnel, 15)

D. H. CHASON
N. W. DORMAN
H. E. HARRIS †
D. M. PALMER

No. 10 ON FORMING TOOLS AND HOLDERS

A.S.M.E. Members (Total personnel, 9)

W. C. MUELLER, *Chairman* †
WILLIAM HARTMAN †
L. D. SPENCE

No. 11 ON CHUCKS AND CHUCK JAWS

A.S.M.E. Member (Total personnel, 10)

J. E. LOVELY, *Chairman* †

SUBGROUP CHAIRMAN

No. 1 on Master Chuck Jaws, J. E. LOVELY
No. 2 on Adapters for Air Cylinders, J. E. LOVELY

No. 12 ON CUT AND GROUND THREAD TAPS

(Total personnel, 7)

No. 13 ON SPLINES AND SPLINED SHAFTS

A.S.M.E. Members (Total personnel, 14)

J. B. ARMITAGE †
R. E. W. HARRISON
F. O. HOAGLAND
J. E. LOVELY †
B. F. WATERMAN

SUBGROUP CHAIRMEN

Machine Tool Splines, R. E. W. HARRISON
Automotive Splines, W. L. BARTH
Involute Splines, C. K. LENNING

No. 17 ON NOMENCLATURE FOR SMALL TOOLS AND MACHINE TOOL ELEMENTS

A.S.M.E. Members (Total personnel, 14)

O. W. BOSTON, *Chairman and Secretary*
F. S. BLACKALL, JR.
F. H. COLVIN †
H. E. HARRIS
F. O. HOAGLAND

Ex-Officio Members

A. N. GODDARD
B. P. GRAVES
W. C. MUELLER †

No. 19 ON SINGLE POINT CUTTING TOOLS

A.S.M.E. Members (Total personnel, 2)

F. H. COLVIN, *Chairman* †
O. W. BOSTON, *Secretary*

No. 20 ON REAMERS

A.S.M.E. Members (Total personnel, 15)

F. H. COLVIN
T. F. GITHENS †
J. H. HORIGAN †

No. 21 ON TOOL-LIFE TESTS FOR SINGLE-POINT TOOLS

(Being organized)

O. W. BOSTON, *Chairman*

GEARS (B6)

** Joint sponsorship with the American Gear Manufacturers Association. Sectional Committee organized June, 1921*

A.S.M.E. Members (Total personnel, 27)

EARLE BUCKINGHAM, *Vice-Chairman* †
C. B. LEPAGE, *Acting Secretary*
G. H. ACKER
U. S. EBERHARDT
L. H. FRY
C. B. HAMILTON, JR.
D. T. HAMILTON
M. R. HANNA
O. A. LEUTWILER †
G. L. MARKLAND, JR.
CARLETON REYNELL

SUBCOMMITTEE CHAIRMEN

No. 1 on Program
No. 2 on Editing Reports
No. 3 on Nomenclature, D. T. HAMILTON
No. 4 on Tooth Form (Spur Gears), U. S. EBERHARDT
No. 5 on Helical Gears, W. P. SCHMITTER
No. 6 on Worm Gears, T. R. RIDEOUT
No. 7 on Bevel Gears, F. L. KNOWLES

GEARS (*Continued*)

No. 8 on Materials, C. B. HAMILTON, JR.
No. 9 on Inspection, J. P. BREUER
No. 10 on Horsepower Rating, EARLE BUCKINGHAM

PIPE FLANGES AND FITTINGS (B16)

** Joint sponsorship with the Heating, Piping, and Air Conditioning Contractors National Association and the Manufacturers Standardization Society of the Valve and Fittings Industry. Sectional Committee organized October, 1921*

A.S.M.E. Members (Total personnel, 49)

C. P. BLISS, *Chairman* †
J. J. HARMAN, *Secretary*
L. W. BENOIT †
A. L. BROWN
SABIN CROCKER
FERDINAND FINK

L. S. MORSE
LUDWIG SKOG
J. R. TANNER †
J. H. TAYLOR
H. L. UNDERHILL
G. W. WATTS
J. H. WILLIAMS

SUBCOMMITTEE CHAIRMEN

No. 1 on Cast Iron Flanges and Flanged Fittings, A. M. HOUSER
No. 2 on Screwed Fittings, F. H. MOREHEAD
No. 3 on Steel Flanges and Flanged Fittings, C. P. BLISS
No. 4 on Materials and Stresses, A. M. HOUSER
No. 5 on Face to Face Dimensions of Ferrous Flanged Valves, J. R. TANNER
No. 6 on Malleable Iron or Steel Brass Seat Unions
No. 7 on Rating of Pipe Fittings
No. 8 on Marking of Pipe Fittings
No. 9 on Port Openings, W. W. HUBBARD

SHAFTING (B17)

** Sole sponsorship. Organized October, 1918*

A.S.M.E. Members (Total personnel, 11)

C. M. CHAPMAN *Chairman* †
H. C. E. MEYER
L. C. MORROW
J. M. SHIMER
G. N. VAN DERHOEF †
L. W. WILLIAMS †

BOLT, NUT, AND RIVET PROPORTIONS (B18)

** Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized March, 1922*

A.S.M.E. Members (Total personnel, 57)

A. E. NORTON, *Chairman* †
H. E. ALDRICH
F. C. BILLINGS
B. G. BRAINE
G. S. CASE
T. G. CRAWFORD
H. P. FREAR
HERMAN KOESTER
S. F. NEWMAN
R. J. WHELAN
E. M. WHITING
V. R. WILLOUGHBY
(J. J. MCBRIDE, *Alternate*)
O. B. ZIMMERMAN

SUBCOMMITTEE CHAIRMEN

No. 1 on Large and Small Rivets
No. 2 on Wrench Head Bolts and Nuts, W. K. MENDENHALL, JR.
No. 3 on Slotted Head Proportions
No. 4 on Track Bolts and Nuts
No. 5 on Round Unslotted Head Bolts (Carriage Bolts), M. C. HORINE
No. 6 on Plow Bolts, O. B. ZIMMERMAN
No. 7 on Body Dimensions and Materials
No. 8 on Nomenclature, G. S. CASE
No. 9 on Socket Head Cap and Set Screws, HERMAN KOESTER

PLAIN AND LOCK WASHERS (B27)

** Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized August, 1925*

A.S.M.E. Members (Total personnel, 37)

EUGENE CALDWELL
T. G. CRAWFORD
B. S. LEWIS †

Wire and Sheet Metal Gages, H. W. TENNEY

SCREW THREADS FOR HOSE COUPLINGS (B33)

** Sole sponsorship. Sectional Committee organized August, 1928*

A.S.M.E. Members (Total personnel, 27)

A. L. BROWN, *Secretary*
A. F. BREITENSTEIN †
J. J. CROTTY
W. L. CURTISS
W. E. DUNHAM †
J. J. HARMAN
(F. C. ERNST, *Alternate*)
A. M. HOUSER
H. C. E. MEYER
J. H. WILLIAMS

SUBCOMMITTEE CHAIRMEN

No. 1 to Draft Recommended Specifications, J. H. HOWLAND
No. 2 on Basic Thread Dimensions, D. R. MILLER

WROUGHT IRON AND WROUGHT STEEL PIPE AND TUBING (B36)

** Joint sponsorship with the American Society for Testing Materials. Sectional Committee organized April, 1928*

A.S.M.E. Members (Total personnel, 44)

H. H. MORGAN, *Chairman*
SABIN CROCKER, *Secretary*
J. S. ADELSON
H. E. ALDRICH
E. L. HOPPING
(A. B. MORGAN, *Alternate*)
A. M. HOUSER †
D. S. JACOBUS †
(F. S. CLARK, *Alternate*) †
J. J. KANTER
H. C. E. MEYER
F. H. MOREHEAD
H. B. OATLEY †
LUDWIG SKOG †
F. N. SPELLER
J. R. TANNER
A. E. WHITE

SUBCOMMITTEE CHAIRMEN

No. 1 on Plan, Scope, and Editing, H. H. MORGAN
No. 2 on Pipe and Tubing for Low Temperature Service, J. J. SHUMAN
No. 3 on Pipe and Tubing for High Temperature Service, J. R. TANNER
No. 4 on Materials, F. H. MOREHEAD

PRESSURE AND VACUUM GAGES (B40)

** Sole sponsorship. Sectional Committee organized July, 1930*

A.S.M.E. Members (Total personnel, 44)

M. D. ENGLE, *Chairman*
A. W. LENDEROTH, *Secretary* †
E. J. BRYANT
J. P. CAVANAUGH †
PAUL DISERENS
C. H. GRAESSER
W. F. JONES
R. J. KEHL
J. C. MCCUNE †
A. H. MORGAN
H. B. REYNOLDS
W. C. SCHOENFELDT

SUBCOMMITTEE CHAIRMEN

No. 1 on Plan and Scope, M. D. ENGLE
No. 2 on Definitions, C. F. SCHWEP
No. 3 on Gage Sizes and Mounting Dimensions, H. B. REYNOLDS
No. 4 on Accuracy and Test Methods, O. J. HODGE

STOCK SIZES, SHAPES AND LENGTHS FOR HOT AND COLD FINISHED IRON AND STEEL BARS (B41)

** Sole sponsorship. Sectional Committee organized April, 1929*

A.S.M.E. Members (Total personnel, 27)

F. H. DECHANT
L. W. WILLIAMS †
G. H. WOODROFFE
O. B. ZIMMERMAN

SUBCOMMITTEE CHAIRMEN

No. 1 on Hot Rolled Steel, HENRY WYSOR
No. 2 on Cold Finished Steels, L. E. CREIGHTON
No. 3 on Hot Rolled Iron

SPECIFICATIONS FOR LEATHER BELTING (B42)

** Sole sponsorship. Sectional Committee organized February, 1931*

A.S.M.E. Members (Total personnel, 28)

H. T. COATES
R. W. DRAKE †
KING HATHAWAY
J. E. RHOADS
G. A. SCHIEREN
O. B. ZIMMERMAN

SUBCOMMITTEE CHAIRMEN

No. 1 on Standard Specifications, R. C. BOWKER
No. 2 on Recommendations for Selection, Care, and Installation, G. A. SCHIEREN

MACHINE PINS (B43)

** Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized March, 1926*

A.S.M.E. Members (Total personnel, 14)

E. J. BRYANT †
J. J. MCBRIDE
H. C. E. MEYER
O. B. ZIMMERMAN

SUBCOMMITTEES

No. 1 on Straight, Taper, and Dowel Pins
No. 2 on Split Pins

CLASSIFICATION AND DESIGNATION OF SURFACE QUALITIES (B46)

** Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized May, 1932*

A.S.M.E. Members (Total personnel, 60)

J. R. WEAVER, *Chairman*
E. J. ABBOTT
E. J. BRYANT
C. S. COLE
T. G. CRAWFORD

A. H. LYON
M. J. REED
F. C. SPENCER
C. C. STEVENS
J. S. TAWRESEY
C. H. WHITAKER
ERNEST WOOLER

SUBCOMMITTEE CHAIRMEN

No. 1 on Surfaces Produced by Tools and Abrasives, JOHN CETRULE
No. 2 on Surfaces Produced by Molds, Dies, Rolls, or Any Other Means of Deforming Materials
No. 3 on Coated Surfaces, G. B. HOGABOOM
No. 4 on Symbols for Indicating Surface Quality on Drawings, T. G. CRAWFORD
No. 5 on Ways, Means, and Apparatus for Measuring Quality of Surface, J. R. WEAVER
No. 6. on Finance, R. E. W. HARRISON

SCHEME FOR IDENTIFICATION OF PIPING SYSTEMS (A13)

** Joint sponsorship with the National Safety Council. Sectional Committee organized June, 1922*

A.S.M.E. Members (Total personnel, 33)

E. E. ASHLEY
W. L. BUNKER
CROSBY FIELD
E. L. HOPPING
H. L. MINER
H. S. SMITH
FRANK THORNTON

SUBCOMMITTEE CHAIRMEN

Identification by Colors
Classification, CROSBY FIELD
Identification Markings Other Than Color

COMBUSTION SPACE FOR SOLID FUELS (B50)

** Sole sponsorship. Sectional Committee organized June, 1933*

A.S.M.E. Members (Total personnel, 21)

C. E. BRONSON, *Chairman*
W. G. CHRISTY
JOHN HUNTER
A. J. JOHNSON
V. G. LEACH †

COMBUSTION SPACE FOR SOLID FUELS (*Continued*)

J. P. Magos
J. F. McIntire
F. L. Meyer
C. A. Reed
John Van Brunt †

SUBCOMMITTEE CHAIRMEN

No. 1 on Purpose and Scope, C. E. Bronson
No. 2 on Combustion and Design, B. M. Guthrie
No. 3 on Warm Air Furnaces, J. H. Manny
No. 4 on Steel Heating Boilers, W. B. Russell
No. 5. on Cast Iron Boilers, J. F. McIntire

MINIMUM REQUIREMENTS FOR PLUMBING AND STANDARDIZATION OF PLUMBING EQUIPMENT (A40)

** Joint sponsorship with the American Society of Sanitary Engineering. Sectional Committee organized August, 1928*

A.S.M.E. Members (Total personnel, 55)

C. B. LePage, *Acting Secretary*
J. F. Carney
C. S. Cole
J. J. Crotty
A. M. Houser
G. W. Martin
(A. H. Morgan, *Alternate*)
W. K. McAfee
W. R. Webster †

SUBCOMMITTEE CHAIRMEN

No. 1 on Minimum Requirements for Plumbing, W. C. Groeniger
No. 2 on Staple Vitreous China Plumbing Fixtures, H. R. Van Sciver
No. 3 on Staple Porcelain (All Clay) Plumbing Equipment, H. R. Van Sciver
No. 4 on Enameled Sanitary Ware, J. J. Hall
No. 5 on Traps, A. R. McGonegal
No. 6 on Brass Plumbing Products, J. L. Murphy
No. 7 on Brass Fittings for Flared Copper Tubes, F. L. Riggin
No. 8 on Cast Iron Soil Pipe and Fittings, J. J. Crotty
No. 9 on Gasoline, Oil, and Grease Separators, J. J. Crotty
No. 11 on Soldered Fittings for Tubing, A. M. Houser
No. 12 on Minimum Air Gaps in Plumbing Systems, W. K. McAfee

Joint Committee on Threaded Cast Iron Pipe, F. H. Morehead

ELECTRIC MOTOR FRAME DIMENSIONS (C28)

** Joint Sponsorship with the National Electrical Manufacturers Association. Sectional Committee organized November, 1927*

A.S.M.E. Members (Total personnel, 29)

C. A. Adams
S. A. Einstein
E. W. Ely
F. S. English
W. F. Jones
A. G. Trumbull †
Rudolph Michel

POWER TEST CODES TECHNICAL COMMITTEES

ARTICLE B6A, PAR. 27: The Standing Committee on Power Test Codes shall, under the direction of the Council, have supervision of all the activities of the Society in connection with the A.S.M.E. Power Test Codes, including the interpretation of such codes.

The first Standing Committee on Power Test Codes was organized in December, 1918, to revise and extend the Power Test Codes which had been formulated by various technical committees appointed to develop particular codes. This work began in 1884.

STANDING COMMITTEE

Reorganized, 1935

PAUL DISERENS, *Chairman*
G. T. FELBECK
C. R. HOUGHTON
J. F. HUVANE
R. M. JOHNSON
J. F. D. SMITH

(10) CENTRIFUGAL AND TURBO-COMPRESSORS AND BLOWERS

Appointed December, 1918
Reorganized, 1929

A. T. BROWN, *Chairman*
E. L. ANDERSON
C. A. BOOTH
W. H. CARRIER
THOMAS CHESTER
L. E. DAY
E. S. DEAN
Z. G. DEUTSCH
S. H. DOWNS
P. E. GOOD
J. J. GROB
H. F. HAGEN
PAUL HOFFMAN

H. D. Kelsey
A. L. Kimball
R. D. Madison
L. S. Marks
Arvid Peterson
H. F. Schmidt
M. C. Stuart

(11) COMPLETE STEAM POWER PLANTS

Appointed December, 1918
Reorganized, 1933

F. M. Van Deventer, *Chairman*
D. S. Wegg, *Secretary*
W. F. Davidson
C. H. Fellows
R. A. Foresman
V. M. Frost
W. W. Johnson
E. W. Norris
H. S. Whiton

(12) CONDENSERS, WATER HEATING, AND COOLING EQUIPMENT

Appointed December, 1918

G. A. Orrok, *Chairman*
P. H. Hardie, *Secretary*
C. H. Baker, Jr.
R. N. Ehrhart
J. F. Grace
D. W. R. Morgan
H. B. Reynolds
P. E. Reynolds

(13) REFRIGERATING SYSTEMS

Appointed December, 1918
Reorganized May, 1939

B. H. Jennings, *Chairman* †
A. C. Buensod
(R. W. Waterfill, *Alternate*)
J. C. Consley
(H. B. Pownall, *Alternate*)
H. A. Feldbush †
Walter Jones †
A. W. Oakley
C. L. Svenson
Frank Zumbro †

(14) EVAPORATING APPARATUS

Appointed December, 1918

E. N. Trump, *Chairman*
B. N. Bump
E. A. Newhall
H. L. Parr
L. C. Rogers

(15) STEAM LOCOMOTIVES

Appointed December, 1918

E. C. Schmidt, *Chairman*
W. F. Kiesel, Jr.

† Official A.S.M.E. representatives serving on this committee.

H. B. Oatley
G. E. Rhoads
L. K. Sillcox
W. E. Woodard

(16) GAS PRODUCERS

Appointed December, 1918

C. D. Smith
H. F. Smith

(17) INTERNAL-COMBUSTION ENGINES

Appointed December, 1918
Reorganized, 1939

Lee Schneitter, *Chairman*
F. H. Dutcher, *Secretary*
J. C. Barnaby
Harte Cooke
H. E. Degler
W. L. H. Doyle
L. R. Ford
L. B. Jackson
E. J. Kates
E. C. Magdeburger
B. V. E. Nordberg
M. J. Reed
Max Rotter
O. D. Treiber

(18) HYDRAULIC PRIME MOVERS

Appointed December, 1918
Reorganized, 1931

S. L. Kerr, *Chairman*
C. M. Allen
L. M. Davis
H. L. Doolittle
W. F. Durand
H. N. Eaton
N. R. Gibson
J. P. Growdon
T. H. Hogg
L. J. Hooper
C. W. Hubbard
E. C. Hutchinson
D. J. McCormack
L. F. Moody
W. J. Rheingans
E. B. Strowger
R. V. Terry
W. M. White

(19) INSTRUMENTS AND APPARATUS

Appointed, December, 1918

W. A. Carter, *Chairman*
C. M. Allen
W. C. Andrae
E. G. Bailey
H. S. Bean
L. J. Briggs
J. D. Davis
K. J. De Juhasz
R. E. Dillon
F. M. Farmer
J. B. Grumbein
W. W. Johnson
W. H. Kenerson
E. S. Lee
E. L. Lindseth
Osborn Monnett
S. A. Moss
R. J. S. Pigott
E. B. Ricketts
W. A. Sloan
R. B. Smith
I. M. Stein

(20) SPEED-RESPONSIVE GOVERNORS

Appointed December, 1921

Francis Hodgkinson, *Chairman*
Harte Cooke
F. H. Rogers

(21) DUST SEPARATING APPARATUS

Appointed October, 1934

M. D. Engle, *Chairman*
Ollison Craig, *Secretary*
E. L. Anderson
A. D. Bailey
H. H. Bubar
W. G. Christy
H. O. Croft
J. M. DallaValle
H. C. Dohrmann
Philip Drinker
J. W. Fehnel
H. F. Hagen
P. H. Hardie
C. W. Hedberg
J. H. Leech
H. E. Macomber
H. B. Meller
H. C. Murphy
B. F. Tillson

BOILER CODE COMMITTEES

ARTICLE B6A, PAR. 26: The Special Committee on Boiler Code shall, under the direction of the Council, have supervision of all the activities of the Society in connection with the A.S.M.E. Codes for Pressure Vessels, including the interpretations of these codes.

The first Special Committee on Boiler Code was organized in September, 1911.

SPECIAL COMMITTEE

D. S. JACOBUS, *Chairman*
E. R. FISH, *Vice-Chairman*
C. W. OBERT, *Honorary Secretary*
M. JURIST, *Acting Secretary*

THE WOMAN'S AUXILIARY TO THE A.S.M.E.

The Woman's Auxiliary to the A.S.M.E. was organized on May 10, 1923, and its Constitution and By-Laws was approved by the Council of the A.S.M.E. on October 27, 1924. The objects of the Auxiliary are to render service to all that pertains to the interest of the profession of mechanical engineering; to cooperate with any committees of the A.S.M.E.; and to assist the sons and daughters of the members of the Society or worthy students of mechanical engineering in obtaining scholarships; and to promote any other objects consistent with the aims or objects of the A.S.M.E.

OFFICERS

President, MRS. GEORGE W. FARNY
First Vice-President, MRS. COLLINS P. BLISS
Second Vice-President, MRS. CALVIN W. RICE
Third Vice-President, MRS. CROSBY FIELD
Fourth Vice-President, MRS. J. PAGE HARBESON
Fifth Vice-President, MRS. HARRY A. SCHWARTZ
Recording Secretary, MRS. CHARLES H. FAY
Corresponding Secretary, MRS. F. M. GIBSON
Treasurer, MRS. A. H. MORGAN

STANDING COMMITTEE CHAIRMEN

Education, MRS. ROY V. WRIGHT
Membership, MRS. GEORGE E. HAGEMANN
Publicity and Custodian, MISS BURTIE HAAR

COUNCIL REPRESENTATIVES

To be appointed

OFFICERS OF LOCAL SECTIONS

BALTIMORE

Chairman, MRS. D. E. DONOVAN
Vice-Chairman, MRS. A. G. CHRISTIE
Secretary, MRS. J. H. BERRYMAN
Treasurer, MRS. LOUIS F. COFFIN

CLEVELAND

Chairman, MRS. HARRY A. SCHWARTZ
Vice-Chairman, MRS. T. F. GITHENS
Secretary, MRS. E. R. MCCARTHY
Treasurer, MRS. H. L. SPENCE

LOS ANGELES

Chairman, MRS. BERNARD TOBEN
Secretary, MRS. WILBUR W. REASER
Treasurer, MRS. WILLIAM T. POWELL

METROPOLITAN

Chairman, MRS. E. C. M. STAHL
First Vice-President, MRS. J. NOBLE LANDIS
Second Vice-President, MRS. R. B. PURDY
Third Vice-President, MRS. W. TALLMADGE
Recording Secretary, MRS. C. H. YOUNG
Corresponding Secretary, MRS. A. C. COONRADT
Treasurer, MRS. CHARLES GUS

PHILADELPHIA

Chairman, MRS. J. PAGE HARBESON, JR.
Vice-Chairman, MRS. E. F. ZEINER
Recording Secretary, MRS. JUSTIN MCCARTHY
Corresponding Secretary, MRS. F. E. WASHBURN
Treasurer, MRS. WILLIAM F. GLIMM

AWARDS

The following paragraphs deal with the medals, awards, scholarships, and loan funds which come within the jurisdiction of the A.S.M.E. Other awards available to Student Members are listed in *Mechanical Engineering*, February, 1938, page 183. The Society also participates with other engineering societies in a number of joint awards. Further details concerning all the awards will be found in a series of articles beginning in the October, 1938, issue of *Mechanical Engineering*.

Honorary Membership, to which persons of acknowledged professional eminence are elected by unanimous vote of Council under the provisions of the By-Laws and Rules. A list of honorary members is given on page RI-37.

Life Membership, which may be conferred by the Council for distinguished service to the Society; or secured by a member by payment for an annuity in accordance with the provisions of the By-Laws.

A.S.M.E. Medal, established by the Society in 1920 to be presented, together with an engraved certificate, for distinguished service in engineering and science. May be awarded for general service in science having possible application in engineering.

Holley Medal, instituted and endowed in 1924 by George I. Rockwood, Past Vice-President of the Society, to be bestowed, together with an engraved certificate, for some great and unique act of genius of engineering nature that has accomplished a great and timely public benefit.

Worcester Reed Warner Medal, provision for which was made in the will of Worcester Reed Warner, Honorary Member of the Society, is a gold medal to be bestowed, together with an engraved certificate, on the author of the most worthy paper received, dealing with progressive ideas in mechanical engineering or efficiency in management.

Melville Medal, established in 1914 by the bequest of Rear-Admiral George W. Melville, Honorary Member and Past-President of the Society, to be presented, together with an engraved certificate, for an original paper or thesis of exceptional merit, presented to the Society for discussion and publication, to encourage excellence in papers. The medal may be presented annually.

Spirit of St. Louis Medal, established by an endowment fund created in 1929 by citizens of St. Louis, Mo., to be awarded for meritorious service in the advancement of aeronautics. This medal will be awarded at the discretion of the Council of the Society at approximately three-year periods upon the recommendation of its Board of Honors and Awards.

Junior Award, annual cash award of $50, established in 1914, from a fund created by Henry Hess, Past Vice-President of the Society, to be presented, together with an engraved certificate, for the best paper or thesis submitted by a Junior Member.

Pi Tau Sigma Medal Award, established in 1938, endowed by Pi Tau Sigma, the national honorary mechanical engineering fraternity, to be presented annually, together with an engraved certificate, to the young mechanical engineer for outstanding achievement in his profession within the ten years after graduation from a regular four-year mechanical engineering course of a recognized American college or university. Any mechanical engineering graduate, not more than thirty-five years of age, whose achievement has been all or in part in any field including industrial, educational, political, research, civic, etc., is eligible.

Charles T. Main Award, annual cash award of $150, established in 1919 from a fund created by Charles T. Main, Past-President of the Society, to be awarded, together with an engraved certificate, to a Student Member of the Society, for the best paper within the general subject of the influence of the profession upon public life. The exact subject is assigned by the Board of Honors and Awards, subject to the approval of the Council, and is announced each year through the Honorary Chairman of the Student Branches.

Student Awards, two annual cash awards of $25 each, established in 1914, from a fund created by Henry Hess, Past Vice-President of the Society, to be presented, together with engraved certificates, for the best papers or theses submitted by Student Members. The awards for 1932 and subsequent years have been given, one for undergraduate and the other for postgraduate work.

SCHOLARSHIPS AND LOAN FUNDS

Max Toltz: Loan Fund of $15,000 established by Major Max Toltz, former member of the Council of the Society, the income to be used for assistance to Student Members.

John R. Freeman: Fund of $25,000 established in 1926 by John R. Freeman, Past-President of the Society, the income to be used for travel scholarships and research.

Woman's Auxiliary: Scholarship or Fellowship offered by the Woman's Auxiliary to the Society to assist sons and daughters of members or worthy students of mechanical engineering.

RECIPIENTS OF AWARDS

The names of the recipients of the different awards to date are given in the following lists, together with the dates of presentation, and the services or papers for which the awards were made. There were no awards for the years not listed.

A.S.M.E. Medal

1921 Hjalmar Gotfried Carlson, in recognition of the services rendered the Government because of his invention and part in the production of 20,000,000 Mark III drawn steel booster casings used principally as a component of 75-mm high-explosive shells, but also used extensively in gas shells and bombs

1922 Frederick Arthur Halsey, for his paper describing the premium system of wage payments presented before the Society at the Providence Meeting in 1891, as the adoption of the methods there proposed has had a profound effect toward harmonizing the relations of worker and employer

1923 John Ripley Freeman, for his eminent service in engineering and manufacturing by his meritorious work in fire prevention and the preservation of property

1926 R. A. Millikan, in recognition of his contributions to science and engineering

1927 Wilfred Lewis, for his contributions to the design and construction of gear teeth

1928 Julian Kennedy, for his services and contributions to the iron and steel industry

1929 William LeRoy Emmet, for his contributions in the development of the steam turbine, electric propulsion of ships, and other power-generating apparatus

1931 Albert Kingsbury, for his research and development work in the field of lubrication

1933 Ambrose Swasey, for his contributions to the advancement of the engineering profession and for his part in the development of the turret lathe and the astronomical telescope

1934 Willis H. Carrier, in recognition of his research and development work in air-conditioning

1935 Charles T. Main, for distinguished achievements in the textile and other industries, in engineering education, and for eminent service to the engineering profession

1936 Edward Bausch, for meritorious mechanical developments in the field of optics

1937 Edward P. Bullard, for outstanding leadership in the development of station-type machine tools

1938 Stephen J. Pigott, for outstanding leadership in marine propulsion and construction

1939 James E. Gleason, for service to the cause of safer and better transportation.

Holley Medal

1924 Hjalmar Gotfried Carlson, for his inventions and processes which made possible the timely production of drawn steel booster casings for artillery ammunition, thereby aiding victory in the World War (diploma in recognition of achievements presented in 1921)

1927 Elmer Ambrose Sperry, for achievements and inventions that have advanced the naval arts, including the gyroscope that has freed navigation from the dangers of the fluctuating magnetic compass

1929 Baron Chuzaburo Shiba, for his contributions to knowledge through fundamental research, including the field of aerodynamics, by the development of ultra-rapid kinematographic methods.

1934 Irving Langmuir, for his contributions to science and engineering, including the development of gas-filled incandescent lamps, thoriated filament for thermionic emission, atomic hydrogen welding, phase control operation of the thyratron tube, and fundamental research in oil films
1936 Henry Ford, for revolutionary influence through invention and practice on transportation and on mass production methods in manufacturing
1937 Frederick G. Cottrell, for preeminent public service—the invention of electric precipitation—advancement of the science of gas liquefaction—gifts for engineering research
1938 Francis Hodgkinson, for meritorious services in the development of the steam turbine
1939 Carl E. Johansson, in recognition of his pioneer work in the development of basic measuring gages.

Worcester Reed Warner Medal

1933 Dexter S. Kimball, for his contributions to efficiency in management as exemplified by his recently revised "Principles of Industrial Organization" and by his many articles, engineering society papers, and public addresses
1934 Ralph E. Flanders, for his contributions to a better understanding of the relationship of the engineer to economic problems and social trends as exemplified by the many papers which he has presented
1935 Stephen Timoshenko, for his contributions to the theory of the design of elastic structures and the treatment of dynamics of moving machinery
1936 Charles M. Allen, for his early and continued hydraulic laboratory work and for the permanent value of the papers on his development of methods of testing large hydraulic turbine installations
1937 Clarence F. Hirshfeld, for his research and contributions to the theory and practice of heat-power engineering as exemplified by books and papers
1938 Lawford H. Fry, for contributions relating to improved locomotive boiler design and utilization of better materials in railway equipment
1939 Rupen Eksergian, for influential papers of permanent value in A.S.M.E. Transactions.

Melville Medal

1927 Leon P. Alford, "Laws of Manufacturing Management"
1929 Joseph W. Roe, "Principles of Jig and Fixture Practice"
1930 Herman Diederichs and William D. Pomeroy, "The Occurrence and Elimination of Surge or Oscillating Pressure in Discharge Lines From Reciprocating Pumps"
1931 Arthur E. Grunert, "Comparative Performance of a Pulverized-Coal-Fired Boiler Using Bin System and Unit System of Firing"
1932 Alexey J. Stepanoff, "Leakage Loss and Axial Thrust in Centrifugal Pumps"
1933 William E. Caldwell, "Characteristics of Large Hell Gate Direct-Fired Boiler Units"
1935 Oscar R. Wikander, "Draft-Gear Action in Long Trains"
1936 H. A. Stevens Howarth, "The Loading and Friction of Thrust and Journal Bearings With Perfect Lubrication"
1937 Alfred J. Büchi, "Supercharging of Internal-Combustion Engines With Blowers Driven by Exhaust-Gas Turbines"
1938 Alphonse I. Lipetz, "Air Resistance of Railroad Equipment"
1939 Lester M. Goldsmith, for his paper, "High-Pressure High-Temperature Turbine-Electric Steamship *J. W. Van Dyke*."

Spirit of Saint Louis Medal

1929 Daniel Guggenheim, founder of the Guggenheim Fund for the Promotion of Aeronautics
1932 Paul Litchfield, for his work in encouraging and sponsoring airship design and construction in this country
1935 Will Rogers, for his splendid, constructive, and unselfish work in the achievement of aviation, and the building up of public confidence in aviation through his articles in the press, over the radio, and from the speaker's platform
1938 James H. Doolittle, for meritorious service in the advancement of aeronautics.

Junior Award

1915 Ernest O. Hickstein, "Flow of Air Through Thin Plate Orifices"
1916 L. M. McMillan, "The Heat Insulating Properties of Commercial Steam-Pipe Coverings"
1919 E. D. Whalen, "Properties of Airplane Fabrics"
1921 S. Logan Kerr, "Moody Ejector Turbine"
1922 R. H. Heilman, "Heat Losses From Bare and Covered Wrought-Iron Pipe at Temperatures up to 800 Degrees Fahrenheit"
F. L. Kallam, "Preliminary Report on the Investigation of the Thermal Conductivity of Liquids"
1923 S. S. Sanford and S. Crocker, "The Elasticity of Pipe Bends"
1924 R. H. Heilman, "Heat Losses Through Insulating Material"
1925 Gilbert S. Schaller, "An Investigation of Seattle as a Location for a Synthetic Foundry Industry"
1927 William M. Frame, "Stresses Occurring in the Walls of an Elliptical Tank Subjected to Low Internal Pressure"
1928 M. D. Aisenstein, "A New Method of Separating the Hydraulic Losses in a Centrifugal Pump"
1929 Arthur M. Wahl, "Stresses in Heavy, Closely Coiled Helical Springs"
1930 Ed Sinclair Smith, "Quantity-Rate Fluid Meters"
1931 M. K. Drewry, "Radiant-Superheater Developments"
1932 Edmond M. Wagner, "Frictional Resistance of a Cylinder Rotating in a Viscous Fluid Within a Coaxial Cylinder"
1933 Townsend Tinker, "Surface Condenser Design and Operating Characteristics"
1934 John I. Yellott, Jr., "Supersaturated Steam"
1935 Stanley J. Mikina, "Effect of Skewing and Pole Spacing on Magnetic Noise in Electrical Machinery"
1936 Harwood F. Mullikan, Jr., "Evaluation of Effective Radiant Heating Surface and Application of the Stefan-Boltzman Law to Heat Absorption in Boiler Furnaces"
1937 Leslie J. Hooper, "American Hydraulic-Laboratory Practice"
1938 Arthur C. Stern, "Separation and Emission of Cinders and Fly Ash."

Pi Tau Sigma Medal

1938 Wilfrid E. Johnson, for his development work in the field of refrigeration
1939 John I. Yellott, Jr., in recognition of significant achievements in steam-flow research and engineering education; also contributions on "Supersaturated Steam" and "Condensation of Flowing Steam in Diverging Nozzles."

Charles T. Main Award

1925 Clement R. Brown, Catholic University of America. Subject: "The Influence of the Locomotive on the Unity of the United States"
1926 W. C. Saylor, Johns Hopkins University. Subject: "The Effect of the Cotton Gin Upon the History of the United States During Its First Seventy Years"
1927 No Award. Subject: "Scientific Management and Its Effect Upon the Industries"
1928 Robert M. Meyer, Newark College of Engineering. Subject: "Scientific Management and Its Effect Upon Manufacturing"
1929 No award. Subject: "The Influence of Engineering on Farm Production"
1930 Jules Podnossoff, Polytechnic Institute of Brooklyn. Subject: "The Value of the Safety Movement in the Industries"
1931 Robert E. Klise, University of Michigan. Subject: "Interchangeability—Its Development and Significance in Industry"
1932 Marshall Anderson, University of Michigan. Subject: "Apprenticeship and Vocational Training"
1933 George D. Wilkinson, Jr., Newark College of Engineering. Subject: "Progress in the Prevention of Smoke and Atmospheric Pollution"
1934 Philip P. Self, Colorado State College, Subject: "Air Conditioning—Its Practicability and Relation to Public Welfare"
1935 G. Lowell Williams, Lafayette College. Subject: "Coordinated Transportation—An Economic Comparison of Railroad, Bus, Truck, Water, and Air Transportation for Long and Short Haul"

1936 No award. Subject: "Development in the Generation and Distribution of Power and Their Effect Upon the Consumer"

1937 ALLAN P. STERN, Case School of Applied Science. Subject: "The Influence of the Introduction of Labor Saving Machinery Upon Employment in the United States"

1938 EDWARD W. CONNOLLY, University of Detroit. Subject: "Economic Limitations in Engineering Design, With Concrete Examples"

1939 JAMES R. BRIGHT, Lehigh University. Subject: "The Economics of Investment in New Manufacturing Equipment—With Concrete Cases."

STUDENT AWARD

1916 BOYNTON M. GREEN, Stanford University, "Bearing Lubrication"
HOWARD E. STEVENS, Rensselaer Polytechnic Institute, "An Investigation of the Dynamic Pressure on Submerged Flat Plates"
M. ADAM, Louisiana State University, "The Adaptability of the Internal Combustion Engine to Sugar Factories and Estates"

1917 H. R. HAMMOND and C. W. HOLMBERG, The Pennsylvania State College, "Study of Surface Resistance With Glass as the Transmission Medium"

1919 C. F. LEH and F. G. HAMPTON, Stanford University, "An Experimental Investigation of Steel Belting"
W. E. HELMICK, Stanford University, "An Experimental Investigation of Steel Belting"

1920 HOWARD G. ALLEN, Cornell University, "Wire Stitching Through Paper"

1921 KARL H. WHITE, University of Kansas, "Forces in Rotary Motors"
RICHARD H. MORRIS and ALBERT J. R. HOUSTON, University of California, "A Report Upon an Investigation of the Herschel Type of Improved Weir"

1923 CHARLES F. OLMSTEAD, University of Minnesota, "Oil Burning for Domestic Heating"
H. E. DOOLITTLE, University of California, "The Integrating Gate: A. Device for Gaging in Open Channels"

1924 GEORGE STUART CLARK, Stanford University, "Two Methods Used for the Determination of the Gasoline Content of Absorption Oils in Absorption Plants"
L. J. FRANKLIN and CHARLES H. SMITH, Stanford University, "The Effect of Inaccuracy of Spacing on the Strength of Gear Teeth"

1925 HARRY PEASE COX, JR., Rensselaer Polytechnic Institute, "A Study of the Effect of End Shape on the Towing Resistance of a Barge Model"
W. S. MONTGOMERY, JR., and E. RAY ENDERS, JR., Pennsylvania State College, "Some Attempts to Measure the Drawing Properties of Metals"

1926 R. E. PETERSON, University of Illinois, "An Investigation of Stress Concentration by Means of Plaster of Paris Specimens"
CECIL G. HEARD, University of Toronto, "Pressure Distribution Over U.S.A. 27 Aerofoil With Square Wing Tips—Model Tests"

1927 ALFRED H. MARSHALL, Princeton University, "Evaporative Cooling"
ROGER IRWIN EBY, University of Washington, "Measurement of the Angular Displacement of Flywheels"

1928 CLARENCE C. FRANCK, Johns Hopkins University, "Condition Curves and Reheat Factors for Steam Turbines"

1929 FRANK VERNON BISTROM, University of Washington, "An Investigation of a Rotary Pump"
WILLIAM WALLACE WHITE, University of Washington, "An Investigation of a Rotary Pump"

1930 GERARD EDEN CLAUSSEN, Polytechnic Institute of Brooklyn, "High-Temperature Oxidation of Steel"
HAROLD L. ADAMS and RICHARD L. STITH, University of Washington, "A Wind Tunnel for Undergraduate Laboratory Experiments"

1931 JULES PODNOSSOFF, Polytechnic Institute of Brooklyn, "Pressure and Energy Distribution in Multi-Stage Steam Turbines Operating Under Varying Conditions"

1932 H. E. FOSTER, JR., University of Tennessee, "Factors Affecting Spray Pond Design" (Undergraduate Award)
WILLIAM A. MASON, Stanford University, "An Experimental Investigation of the Flame Propagation in Internal-Combustion Engines" (Postgraduate Award)

1933 HUGO V. CORDIANO, Polytechnic Institute of Brooklyn, "Thermal Analysis of Lithium-Magnesium System of Alloys" (Undergraduate Award)
JAMES A. OSTRAND, JR., Princeton University, "Sudden Enlargement in the Open Channel" (Postgraduate Award)

1934 H. REYNOLDS HUDSON, Georgia School of Technology, "Dynamic Balance and Functional Utility Applied to Automotive Design" (Undergraduate Award)

1935 CHARLES P. BACHA, Rutgers University, "The Behavior of Metals Subjected to Combined Stress" (Postgraduate Award)
ROBERT W. BEAL, Oregon State College, "Do Lubricating Oils Wear Out?" (Undergraduate Award)

1936 LEON B. STINSON, Oklahoma Agricultural and Mechanical College, "Polymerized Motor Fuels; Their Economic Significance" (Undergraduate Award)
DEWITT D. BARLOW, JR., Princeton University, "The Critical Speeds of Lateral Vibrations of Shafts With Gyroscopic Effects" (Postgraduate Award)

1937 GINO J. MARINELLI, Rensselaer Polytechnic Institute, "Investigation of the Towing Resistance of a Model Submarine Hull" (Undergraduate Award)

1938 MARSHALL C. LONG, Princeton University, "An Investigation Into the Angular Characteristics of an Adjustable Blade Current Meter" (Postgraduate Award)
DONALD C. MCSORLEY, Michigan State College, "Humidity Insulation" (Undergraduate Award)

1939 DAVID T. JAMES, Michigan State College, "Bells—Concerning Their Tones" (Undergraduate Award).

FREEMAN TRAVEL SCHOLARSHIP

1927 HERBERT N. EATON
1928 BLAKE R. VAN LEER
1929 ROBERT T. KNAPP
1931 REGINALD WHITAKER
1932 G. ROSS LORD
1933, 1934 H. J. CASEY
1935, 1936 VICTOR L. STREETER

HONORARY MEMBERS

HONORARY MEMBERS IN PERPETUITY

ALEXANDER LYMAN HOLLEY, Founder of the Society. Died 1882.

JOHN EDSON SWEET, Founder of the Society. Died 1916.

HENRY ROSSITER WORTHINGTON, Founder of the Society. Died 1880.

DECEASED HONORARY MEMBERS

	ELECTED	DIED
HORATIO ALLEN	1880	1889
SIR WILLIAM ARROL	1905	1913
SIR JOHN AUDLEY FREDERICK ASPINALL	1911	1937
WILLIAM WALLACE ATTERBURY	1925	1935
SIR BENJAMIN BAKER	1886	1907
JOHANN BAUSCHINGER	1884	1893
SIR HENRY BESSEMER	1891	1898
SIR FREDERICK JOSEPH BRAMWELL	1884	1903
JOHN ALFRED BRASHEAR	1908	1920
GUSTAVE CANET	1900	1908
ANDREW CARNEGIE	1907	1919
DANIEL KINNEAR CLARK	1882	1896
RUDOLPH JULIUS EMMANUEL CLAUSIUS	1882	1888
SIR JOHN GOODE	1889	1892
PETER COOPER	1882	1883
CHARLES DE FRÉMINVILLE	1919	1936
CARL GUSTAF PATRICK DE LAVAL	1912	1913
RUDOLPH DIESEL	1912	1913
JAMES DREDGE	1886	1906
VICTOR DWELSHAUVERS-DERY	1886	1913
THOMAS ALVA EDISON	1904	1931
ALEXANDRE GUSTAVE EIFFEL	1889	1923
MARSHAL FERDINAND FOCH	1921	1929
SIR CHARLES DOUGLAS FOX	1900	1921
JOHN RIPLEY FREEMAN	1932	1932
JOHN FRITZ	1900	1913
MAJOR-GENERAL GEORGE WASHINGTON GOETHALS	1917	1928
FRANZ GRASHOF	1884	1893
REAR-ADMIRAL ROBERT STANISLAU GRIFFIN	1920	1933
OTTO HALLAUER	1882	1883
CHARLES HAYNES HASWELL	1905	1907
NATHANAEL GREENE HERRESHOFF	1921	1938
FRIEDRICH GUSTAV HERRMANN	1884	1907
GUSTAV ADOLPH HIRN	1882	1890
JOSEPH HIRSCH	1889	1901
IRA N. HOLLIS	1928	1930
ROBERT WOOLSTON HUNT	1920	1923
BENJAMIN FRANKLIN ISHERWOOD	1894	1915
HENRI LÉAUTÉ	1891	1916
ERASMUS DARWIN LEAVITT	1915	1916
HENRI LE CHATELIER	1927	1936
ANATOLE MALLET	1912	1919
CHARLES H. MANNING	1913	1919
REAR-ADMIRAL GEORGE WALLACE MELVILLE	1910	1912
THE HONORABLE SIR CHARLES ALGERNON PARSONS	1920	1931
CHARLES TALBOT PORTER	1890	1910
AUGUSTE C. E. RATEAU	1919	1930
SIR EDWARD J. REED	1882	1906
FRANZ REULEAUX	1882	1905
CALVIN WINSOR RICE	1931	1934
PALMER C. RICKETTS	1931	1934
HENRI ADOLPHE-EUGENE SCHNEIDER	1882	1898
CHARLES M. SCHWAB	1918	1939
C. WILLIAM SIEMANS	1882	1883
VISCOUNT EI-ICHI SHIBUSAWA	1929	1931
AMBROSE SWASEY	1916	1937
ELIHU THOMSON	1930	1937
HENRY ROBINSON TOWNE	1921	1924
HENRI TRESCA	1882	1885
WILLIAM CAWTHORNE UNWIN	1898	1933
OSKAR VON MILLER	1912	1934
FRANCIS A. WALKER	1886	1897
WORCESTER REED WARNER	1925	1929
GEORGE WESTINGHOUSE	1897	1914
SIR WILLIAM HENRY WHITE	1900	1913
SIR ALFRED FERNANDEZ YARROW	1914	1932

LIVING HONORARY MEMBERS

	ELECTED
LORENZO ALLIEVI	1937
EDMUND BRUCE BALL	1939
HUTCHINSON I. CONE	1936
MORTIMER ELWYN COOLEY	1928
ALEX DOW	1936
WILLIAM FREDERICK DURAND	1934
HERBERT CLARK HOOVER	1925
DAVID SCHENCK JACOBUS	1934
MASAWO KAMO	1929
DEXTER SIMPSON KIMBALL	1939
CHARLES THOMAS MAIN	1939
GEORGE A. ORROK	1936
GRANDE UFFICIALE ING. PIO PERRONE	1920
EDWIN JAY PRINDLE	1939
WILLIAM H. TSCHAPPAT	1938
SAMUEL MATTHEWS VAUCLAIN	1920
HENRY HAGUE VAUGHAN	1939
RIGHT HONORABLE LORD WEIR	1920
ORVILLE WRIGHT	1918

PAST-PRESIDENTS

A list of past vice-presidents, managers, treasurers, and secretaries will be found in the 1930 Record and Index, pages 10-12. Dates in parentheses denote year of death.

ALEXANDER LYMAN HOLLEY, *Chairman of the Preliminary Meeting for Organization of The American Society of Mechanical Engineers* (1882)

1880–1882 ROBERT HENRY THURSTON (1903)
1883 ERASMUS DARWIN LEAVITT (1916)
1884 JOHN EDSON SWEET (1916)
1885 JOSEPHUS FLAVIUS HOLLOWAY (1896)
1886 COLEMAN SELLERS (1907)
1887 GEORGE H. BABCOCK (1893)
1888 HORACE SEE (1909)
1889 HENRY ROBINSON TOWNE (1924)
1890 OBERLIN SMITH (1926)
1891 ROBERT WOOLSTON HUNT (1923)
1892 CHARLES HARDING LORING (1907)
1893–1894 ECKLEY BRINTON COXE (1895)
1895 EDWARD F. C. DAVIS (1895)
1895 CHARLES ETHAN BILLINGS (1920)
1896 JOHN FRITZ (1913)
1897 WORCESTER REED WARNER (1929)
1898 CHARLES WALLACE HUNT (1911)
1899 GEORGE WALLACE MELVILLE (1912)
1900 CHARLES HILL MORGAN (1911)
1901 SAMUEL T. WELLMAN (1919)
1902 EDWIN REYNOLDS (1909)
1903 JAMES MAPES DODGE (1915)
1904 AMBROSE SWASEY (1937)
1905 JOHN RIPLEY FREEMAN (1932)
1906 FREDERICK WINSLOW TAYLOR (1915)
1907 FREDERICK REMSEN HUTTON (1918)
1908 MINARD LAFEVER HOLMAN (1925)
1909 JESSE MERRICK SMITH (1927)
1910 GEORGE WESTINGHOUSE (1914)
1911 EDWARD DANIEL MEIER (1914)
1912 ALEXANDER CROMBIE HUMPHREYS (1927)
1913 WILLIAM FREEMAN MYRICK GOSS (1928)
1914 JAMES HARTNESS (1934)
1915 JOHN ALFRED BRASHEAR (1920)
1916 DAVID SCHENCK JACOBUS
1917 IRA NELSON HOLLIS (1930)
1918 CHARLES THOMAS MAIN
1919 MORTIMER ELWYN COOLEY
1920 FRED J. MILLER (1939)
1921 EDWIN S. CARMAN
1922 DEXTER SIMPSON KIMBALL
1923 JOHN LYLE HARRINGTON
1924 FREDERICK ROLLINS LOW (1936)
1925 WILLIAM FREDERICK DURAND
1926 WILLIAM LAMONT ABBOTT
1927 CHARLES M. SCHWAB (1939)
1928 ALEX DOW
1929 ELMER AMBROSE SPERRY (1930)
1930 CHARLES PIEZ (1933)
1931 ROY V. WRIGHT
1932 CONRAD N. LAUER
1933 A. A. POTTER
1934 PAUL DOTY (1938)
1935 RALPH E. FLANDERS
1936 WILLIAM L. BATT
1937 JAMES H. HERRON
1938 HARVEY N. DAVIS
1939 ALEXANDER G. CHRISTIE

Index to Society Records, Part 1

The page numbers in this section are preceded by the letters "RI," which are omitted in the following index.

Abbreviations and Symbols, Graphical, Comm. 26
Abbreviations and Symbols, Letter, Comm. 26
Abrasive Wheels, Rep. on Safety Comm. 28
Acoustical Measurements, Reps. on Comm. 27
Admissions Comm. 2
Advertising Manager, A.S.M.E. 1
Aeronautic Div., Comms. 6
Aeronautics, Rep. on Standardization Comm. 27
Aims and Objectives, Comm. 4
Air Conditioning, Comm. 8
Alfred Noble Prize, A.S.M.E. Rep. 5
Allowances and Tolerances, Gages, Comm. 22
American Association for the Advancement of Science, A.S.M.E. Reps. 5
American Engineering Council, A.S.M.E. Reps. 5
American Standards Association, A.S.M.E. Reps. 5
American Year Book Corporation, A.S.M.E. Rep. 5
Applied Mechanics Div., Comms. 6
A.S.M.E. Medal
Recipients 34
Statement about 34
Assistant Secretaries, A.S.M.E. 1
Awards, A.S.M.E.
Recipients 34
Statements about 34
Awards Comm. *See* Honors and Awards Comm.
Ball and Roller Bearings, Comm. 22
Biography Advisory Comm. 3
Board of Review 4
Board of Technology 4
Boiler Code
Comm., Special 3, 32
Conference Comm. 32
Exec. Comm. 32
Revision of Section VIII, Special Comm. 33
Subcomms. 32
Boiler Feedwater Studies, Comm. 20
Boiler Furnace Refractories, Comm. 21
Boiler Furnaces, Radiant Heat, Comm. 21
Boilers, Power 32
Boilers, Rules for Inspection of, Comm. 32
Boilers, Special Design of, Comm. 32
Bolted Flanged Connections, Rules for, Comm. 33
Bolt, Nut, and Rivet Proportions, Comm. 24
Building Code for Light and Ventilation, Rep. on Comm. 27
Cast Iron Pipes, Reps. on Comm. 27
Cavitation, Comm. 7
Center for Safety Education, A.S.M.E. Rep. 5
Charles T. Main Award
Recipients 35
Statement about 34
Chucks and Chuck Jaws, Comm. 23
Citizenship Comm. 4
Coal, Classification of, Rep. on Comm. 27
Coal, Clean Bituminous, Rep. on Comm. 27
Coal-Handling Equipment, Rep. on Comm. 27
Coal Mines, Drainage, Rep. on Comm. 27
Colleges, Relations With, Comm. 2, 18
Compressed Air, Work in, Rep. on Safety Comm. 29
Compressed Air Machinery and Equipment, Safety Comm. 28
Compressors and Blowers
Centrifugal and Turbo, Comm. 30
Displacement, Comm. 30
Comptroller, A.S.M.E. 1
Condensers, Water Heating, and Cooling Equipment, Comm. 31
Condenser Tubes, Comm. 21
Constitution and By-Laws Comm. 2
Construction Work, Rep. on Safety Comm. 28
Conveyors and Conveying Machinery, Safety Comm. 28
Coordinating Comm. (Corrosion), Rep. on. 21
Coordination Comm. (Boiler Code) 33
Coordination Comm. (Heat Transfer) 6
Correlating Comm. A.S.A. Safety Code, Rep. on Comm. 28
Corrosion, Coordinating Comm., Rep. on 21
Corrosion, Rep. on Comm. 21
Cottonseed Processing, Comm. 21
Council, A.S.M.E.
Exec. Comm. 1
Members of 1
Special Comms. 4
Cranes, Derricks, and Hoists, Safety Comm. 28
Cut and Ground Thread Taps, Comm. 23
Cutting Metals, Comm. 7, 20
Cutting Tools, Single Point, Comm. 23
Daniel Guggenheim Medal Fund, Inc., A.S.M.E. Reps. 5
Definitions and Values, Power Test Codes, Comm. 30
Depreciation 4
Dimensional Limits and Allowances, Comm. 9
Displacement Pumps, Reciprocating Steam-Driven, Comm. 30
Drawings and Drafting Room Practice, Comm. 26
Drying, Comm. 8
Dues-Exempt Members' Contributions, Comm. 4
Dust Explosions, Reps. on Safety Comm. 29
Dust Separating Apparatus, Comm. 31
Economic Status of the Engineer Comm. 4
Edison Foundation, A.S.M.E. Rep. 5
Editor, A.S.M.E. 1
Education and Training for the Industries Comm. 2
Education, Comm. 4
Electrical Definitions, Rep. on Comm. 27
Electric Motor Frames, Comm. 26
Electric Sockets and Lamp Bases, Comm. 26
Electric Welding Apparatus, Rep. on Comm. 27
Elevators, Comm. 20
Elevators, Safety Code, Comm. 28
Engineering Foundation, A.S.M.E. Reps. 5
Engineering History Comm., A.S.M.E. Reps. 5
Engineering Registration, National Bur. of, A.S.M.E. Rep. 5
Engineering Societies, Cooperation in Safety Work, Rep. on Comm. 28
Engineering Societies Employment Service, A.S.M.E. Reps. 5
Engineers' Council for Professional Development, A.S.M.E. Reps. 5
Evaporating Apparatus, Comm. 31
Exhaust Systems, Rep. on Safety Comm. 28
Feedwater, Boiler Code Comm. 33
Feedwater Studies, Boiler, Comm. 20
Ferrous Materials, Comm. 32
Finance Comm. 2
Fire Tests, Building Construction and Materials, Rep. on Comm. 27
Floor and Wall Openings, Railings, and Toe Boards, Safety Comm. 28
Fluid Meters, Comm. 20
Food Processing, Comm. 8
Forest Fire Protection, Rep. on Comm. 27
Forging and Hot Metal Stamping, Rep. on Safety Comm. 28
Foundry Practice, Comm. 7
Freeman Fund, Comm. 4
Freeman Scholarships. *See* John R. Freeman Travel Scholarships
Fritz Medal Board of Award, A.S.M.E. Reps. 5
Fuels, Calorific Values, Rep. on Comm. 31
Fuels, Power Test Code Comm. 30
Fuels Div., Comms. 6
Fuel Values, Joint Comm., A.S.M.E. Reps. 5, 31
Fusion Welding Requirements. 33
Gages, Pressure and Vacuum, Comm. 25
Gantt Medal Board of Award, A.S.M.E. Reps. 5
Gas Burning Appliances, Rep. on Comm. 27
Gas Mask Canisters, Rep. on Safety Comm. 28
Gas Producers, Comm. 31
Gear Lubricants, Rep. on Comm. 27
Gears, Comm. 23
Gear Teeth, Strength of, Comm. 20
George Westinghouse Bust Comm. 4
Glass, Safety, Rep. on Comm. 29
Graphic Arts Div., Comms. 6
Graphic Presentation Comm. 26
Guggenheim Medal Fund, A.S.M.E. Reps. 5
Heating Boilers, Comm. 32
Heat Transfer Professional Group, Comms. 6
Holley Medal
Recipients 34
Statement about 34
Holmes Safety Association, A.S.M.E. Rep. 5
Honorary Members, List of 37
Honorary Membership, Statement about 34
Honors and Awards Comm. 2
Honors and Awards, Special Comm. of Board of 3
Hoover Medal Board of Award, A.S.M.E. Reps. 5
Hose Couplings, Screw Threads, Comm. 25
Hydraulic Div., Comms. 7
Hydraulic Prime Movers, Comm. 7, 31
Hydraulics, General, Comm. 7
Industrial Instruments and Regulators, Comm. 8
Industrial Workers, Foundries, Protection of, Rep. on Safety Comm. 29
Industrial Workers, Protection of, Rep. on Safety Comm. 29
Industries, Education and Training for, Comm. 2
Instruments and Apparatus, Power Test Codes, Comm. 31
Internal-Combustion Engines, Comm. 31
International Electrotechnical Commission, A.S.M.E. Reps. 5
Iron and Steel Bars, Comm. 25
Iron & Steel Div., Comms. 7
Jig Bushings, Comm. 23
John Fritz Medal Board of Award, A.S.M.E. Reps. 5
John R. Freeman Travel Scholarships

Memorial Biographies

SOCIETY RECORDS—Part II

Part I of Society Records for the year 1940, containing Council and Committee personnel and other general information, was issued as Section Two of the Transactions for February, 1940. Part II is published for inclusion with all bound copies of Volume 62 of the Transactions and distributed to members of the Society upon request.

OCTOBER, 1940

VOL. 62, NO. 7

Transactions

of The American Society of Mechanical Engineers

Published on the tenth of every month, except March, June, September, and December

Memorial Biographies

THE purpose of Memorial Biographies is to place on permanent record the biographical and professional data relating to deceased members of The American Society of Mechanical Engineers. Hence every effort is expended to insure accuracy, and to make the memorials as inclusive as is reasonably possible.

The first source of information upon which these notices are based is the Society's file of membership applications and transfers. In the case of the more recent member, these application records are fairly complete. The applications of those who became members many years ago, however, contain less detailed data, and in many cases the sponsors are no longer alive, so that it is difficult to obtain assistance from this source. If the member has been retired for several years prior to his death, his business associates are frequently hard to locate, and, in some cases, members of his family cannot be found. While all these factors add to the difficulty of obtaining accurate and fairly complete data, every possible source of information is explored, with the result that publication of the notice is sometimes delayed. A number of the memorials in this issue have been prepared under these difficulties.

It is the practice of the Committee on Publications in the case of some deceased members to ask former friends and associates to prepare the obituary. The object is to secure a final record that will be more valuable for having been prepared by men who knew the deceased and are competent to evaluate his work. Memorials prepared in accordance with this policy are signed by those who wrote them or who collaborated in their preparation. To all persons who have thus cooperated, the Committee acknowledges its gratitude.

The Committee also appreciates and acknowledges the assistance that has been given by relatives, business associates, and friends in the preparation of all other memorials. It also acknowledges its debt to such sources as Who's Who in Engineering, Who's Who in America, and similar publications; the Encyclopedia of American Biography, and the National Cyclopedia of American Biography; the technical and daily press; colleges and universities and their alumni associations; and engineering and other societies which have supplied information from their records.

Relatives, business associates, and Local Section and Student Branch officers are urged to notify the Society promptly of the deaths of members. Newspaper clippings or obituaries in any other form should be sent whenever available and the names and addresses of those who can supply further information should be furnished. A special form for supplying complete details will be forwarded by the Office of the Society upon request.

THE COMMITTEE ON PUBLICATIONS

Memorial Biographies

GEORGE PENNELL ABORN (1863–1938)

George Pennell Aborn, in charge of the Industrial Department of the Harvard Trust Company, Cambridge, Mass., died on July 7, 1938, of coronary thrombosis, at Waban, Mass.

Mr. Aborn was born at Wakefield, Mass., on June 8, 1863, the son of George W. and Mary Frances (Pennell) Aborn. He prepared for college in the Wakefield High School, followed by one year at the Phillips Academy, Andover, Mass., and was graduated in mechanical engineering from the Massachusetts Institute of Technology in 1886, with the B.S. degree. During his college years he was employed in the vacation periods in the office of Percy M. Blake, waterworks consulting engineer of Boston, and there gained early practical experience which was a valuable asset in his later work.

In October of 1886, Mr. Aborn went to work as draftsman at the Knowles Steam Pump Works, Warren, Mass., advancing to assistant constructing engineer in 1890.

The following account of his work from then until the end of 1926, when his fortieth anniversary with the company was celebrated, is taken from "Simplexities," the Blake and Knowles house organ, December, 1926.

"It was at about this time that the compound duplex direct-acting pump was being looked upon with general favor as the most suitable type of engine for municipal water works pumping stations and for large mining service, and Mr. Aborn was responsible for the design and successful operation of the many units, some of them the largest ever made in the history of direct-acting pumping engine manufacture, for which the Knowles Works was justly well known in those days. He developed and patented a high-duty pumping engine at this period which showed much higher economy than the direct-acting pumps as regularly built, but the gradual introduction of flywheel pumping engines for large water pumping duty prevented further development along this line.

"Mr. Aborn also invented and patented many improvements in pumping machinery, air compressors, and power-plant auxiliaries which became adopted practice in the Knowles product. Of a generally inventive mind, his activities naturally overflowed to outside lines and several patents stand to his credit covering devices of a widely varied character.

"In 1896, Mr. Aborn was made chief engineer and assistant to the manager. When the Knowles Steam Pump Works was consolidated with the George F. Blake Manufacturing Company, at East Cambridge in 1897, the title of the company then becoming Blake and Knowles Steam Pump Works, Mr. Aborn was made assistant manager and chief engineer of the combined plants, and in 1905, he became manager of the Blake and Knowles Steam Pump Works (now the Blake and Knowles Works of the Worthington Pump and Machinery Corporation).

"During this East Cambridge period, Mr. Aborn's inventive genius has from time to time manifested itself in valuable improvements applied to the various lines of product built by the company, covering sinking pumps, air compressors, attachments and unloaders, exhaust relief valves, engine valves, a turbinated pump valve, novel arrangements of compound steam ends, etc. He was one of the first to investigate the possibilities of a combined wet and dry vacuum pump.

"Mr. Aborn has always been deeply interested in the matter of steam valve gearing, and has given much attention to the subject, particularly with reference to the operation of single pumps, and has devised many improvements in the means of accomplishing satisfactory valve movements, among them being the well-known simplex style 'A' gear which for twelve years has been adopted as the standard for all Blake-Knowles single pumps, and entirely supersedes both the original Knowles and the Blake types. All the thousands of simplex pumps built for the Naval program during the past war were equipped with this gear, and its great popularity with naval engineers and with pump operators generally is a sufficient testimonial of its excellence.

"Mr. Aborn has also developed a simplex cut-off valve gear, a radical departure in direct-acting pump operation which has shown an increase of efficiency and decrease in steam consumption amounting to from 15 to 20 per cent."

In February, 1928, after the East Cambridge plant closed, Mr. Aborn joined the staff of the Harvard Trust Company, Cambridge, Mass., in its Industrial Department, and subsequently was appointed manager, which position he was holding at the time of his death.

Mr. Aborn joined the A.S.M.E. as a junior in 1889, and was promoted to the member grade in 1892. He was also a member of the Society of Naval Architects and Marine Engineers and of the American Society of Naval Engineers. He was a past-president of the Boston Branch of the National Metal Trades Association, of the New England Foundrymen's Association, and of the American Association of Foundrymen. In 1931–1933 he was treasurer of the Cambridge Industrial Association and he served as its president in 1933–1934. He also belonged to the Masonic fraternity and to a number of Boston clubs, including the Engineers and University.

In 1890, Mr. Aborn married Maude Nutting Powers, of Warren, who survives him, together with their two children, Rachel (Aborn) Andersen and Pennell N. Aborn.

HARALD AHLQVIST (1876–1938)

Harald Ahlqvist, consulting engineer, New York, N.Y., died of coronary thrombosis, on September 6, 1938, at Kingston, Jamaica, while on a West Indian cruise. Mr. Ahlqvist was born on October 16, 1876, in Fredrikshamn, Finland, the son of Carl Henrik and Anna Luisa Ahlqvist. He attended the Real Lyceum, Fredrikshamn, and a school in Hamburg, Germany, and in 1901 was graduated in mechanical engineering from the Royal Polytechnicum, Dresden, Germany.

From March, 1896, to March, 1898, he served an apprenticeship at machine building in the works of Sulzer Brothers, Winterthur, Switzerland, and during 1899 was in military training in the Finnish Dragoons. For three months in 1900 he was employed in the drafting room of Berliner Maschinenbau, Berlin, Germany. In 1901, Mr. Ahlqvist came to the United States and was employed by the Southwark Foundry & Machine Co., Philadelphia, Pa., and by the Sharon Steel Co., Sharon, Pa., designing rod and wire machines, especially those used for producing barbed wire and wire netting. This was followed by a term as engineer for the Compania Industria de Turba in Mexico (November, 1903, to May, 1904), erecting a plant and installing machinery for peat briquetting. From then until August, 1905, he was engineer for Oficina Technica Pablo Bergner S. en C., Mexico, D.F., testing and designing mining and milling machinery, milling plants, and plants for the manufacture of rubber from guayule.

In 1906, he returned to the United States and joined the staff of Semet-Solvay Company, and the Solvay Process Company, Syracuse, N.Y., as designing engineer. He remained with this firm until 1922, becoming superintendent of operations in 1908 and assistant to the general manager in 1918. In 1919 he made a survey for the company in the Southwest which led to the establishment of three large alkali plants in Louisiana and Texas.

In 1922, Mr. Ahlqvist opened his own office as consulting engineer, specializing in the design, construction, and operation of soda ash, caustic soda, sodium bicarbonate, calcium chloride, and potassium chloride plants, lime kilns, and the manufacture of alkaline products in general. He designed and built plants in the United States and many other parts of the world, including Mexico, Venezuela, Germany, and Japan. He also remodelled and modernized the equipment of many plants, among which was the Mathieson Alkali Works, at Saltville, Va. He had taken out patents on an ammonia still, a sulphur recovery process, and a clarifier, designed primarily for ammonia soda liquors but usable for filtering other liquids.

Mr. Ahlqvist joined the A.S.M.E. as a member in 1909. He was also a member of the American Institute of Mining and Metallurgical Engineers, American Chemical Society, and American Institute of Chemical Engineers. His clubs included the Chemists' Club, New York, and the Apawamis, Manursing, and American Yacht clubs of Rye, N.Y., where he had for many years made his home. He was a fluent linguist, speaking not only his native tongue and English, but Swedish, French, and German as well. He became an American citizen in June, 1912, at Syracuse, N.Y.

He married, in 1903, Eleanor St. Barbe Pattee, of Brookline, Mass., now residing in San Diego, Calif.

SAMUEL AITKEN (1882–1938)

Samuel Aitken, vice-president of Moore & McCormack Co., Inc., (now Moore-McCormack Lines, Inc.), steamship agents, New York, N.Y., died on August 12, 1938.

Mr. Aitken was born on July 21, 1882, in Belfast, Ireland, the son of Robert and Annie (Kane) Aitken. He attended Belfast schools, including the Academical Institute, and then served as apprentice engineer in the famous shipyards of Harland & Wolff, Belfast, covering the years 1897–1902. At the completion of this training, Mr. Aitken went to sea as junior engineer, and continued in service with the White Star Line and the Pacific Mail Steamship Company until 1916, advancing to the position of chief engineer. In 1911, he was chief engineer of the S.S. *Asia* when it was wrecked on Finger Rocks in the

China Sea. Mr. Aitken, together with the captain and chief officer, spent the whole night fighting off Chinese pirates, during which they fired some five-hundred rounds of ammunition. The vessel had on board more than 200 passengers, all of whom were landed safely, and the cargo was kept intact.

In 1916–1917 Mr. Aitken was assistant superintendent of repairs for the Moore & Scott Iron Works, San Francisco, Calif. From then until 1919, he was employed by the U.S. Shipping Board, first as assistant to its representative in the Far East, stationed at Manila, where he was in charge of repairing interned German ships, and later as engineer-representative of the Board of Inspection and port engineer for the North Atlantic district. He organized the Engineering Department of the Board of Inspection and as its senior engineer had charge of the supervision of maintenance and personnel of U.S. Shipping Board vessels in the department. The Inspection Board, which investigated all accidents, strandings, etc., covered, during the latter part of 1918, New York, Philadelphia, Baltimore, Norfolk, and Newport News. Mr. Aitken's duties as post engineer were similar to those for the Board of Inspection.

In 1919, Mr. Aitken was appointed superintendent-engineer of Moore & McCormack Co., Inc., steamship agents, in charge of the Engine Department and of repairs and new construction in all departments of vessels controlled by the company. He was elected vice-president of the company in 1923. During the time he served the company in that office he made alterations to the Hog Island type of vessel to raise its speed from the 11 knots for which it was designed to maintain a sea speed of $13^1/_2$ knots. In this connection, Mr. Aitken took out several patents, foremost among which was the "drag eliminator," which was a form of streamlining around the stern post and rudder of the vessel.

Mr. Aitken joined the A.S.M.E. as an associate-member in 1921, and in 1924 was promoted to the member grade. Besides his membership in the A.S.M.E., he was also a civil member of the Society of Naval Engineers, and a member of the Society of American Military Engineers, the Society of Naval Architects and Marine Engineers, and the Institution of Marine Engineers of Great Britain. In 1936, he was appointed by the U.S. Secretary of Labor as the delegate to the International Maritime Labor Conference at Geneva, representing American steamship owners. He was also a member of the Board of Visitors of the New York State Merchant Marine Academy. He belonged to the Shackmaxon Country Club and Downtown Athletic Club. He held licenses as chief engineer from both the British and American governments. Though born in Ireland, he was a citizen of the United States.

In 1910, Mr. Aitken married Margaret Eugenia Scott, a native of Philadelphia, and is survived by her and by their son, George Robert Aitken.

WILLIAM ALEXANDER, II (1910–1938)

William Alexander, II, production foreman, Scott Paper Company, Chester, Pa., died on February 6, 1938, at Hackensack, N.J.

Mr. Alexander was born in Edinburgh, Scotland, on November 24, 1910, the son of William and Annisabel (Cox) Alexander. As a child, he emigrated with his parents to the United States, and he obtained his preparatory education in the Hasbrouck Heights, N.J., high school. He later attended the Rensselaer Polytechnic Institute for two years and the Massachusetts Institute of Technology, where he was graduated with the degree of B.S. in mechanical engineering, in 1932. He later did postgraduate work in accounting at the University of Pennsylvania.

Immediately after the completion of his technical education, Mr. Alexander went to work for the Scott Paper Company, Chester. From August, 1932, to December of that year he operated a paper converting machine; from then until July, 1934, he worked in the cost department; and in July, 1934, he was promoted to production foreman, the position he held at the time of his death.

Mr. Alexander joined the A.S.M.E. as a junior in 1932. He was an American citizen due to his father's being naturalized while he, the son, was a minor. He was unmarried.

GEORGE FRANCIS ANDERSON (1884–1938)

George Francis Anderson, chief engineer of England-Walton & Co., Hazelwood, N.C., died in Philadelphia, Pa., on June 23, 1938.

Mr. Anderson was born in Oakland, Calif., on October 20, 1884, the son of John Francis and Maria Agnes Anderson. His education was obtained in the public high school, followed by classes at the Humbolt Evening Technical School, and he served a four-years' apprenticeship as machinist, 1901–1904, with the Risdon Iron Works, San Francisco. He then spent about twelve years at sea, first as assistant engineer with the American-Hawaiian and Pacific Mail Steamship Line, 1905–1912, and during the next four years as chief engineer for the Eschen & Minor Steamship Co. During the year 1916–1917, Mr. Anderson was employed as lubrication and sales engineer by the Texas Oil Company, and Standard Oil Company of California. In 1918, he was a first lieutenant in the Air Service of the U.S. Army. From 1919 to 1925 he served at Philadelphia as senior inspector of hulls and machinery for the U.S. Shipping Board, Emergency Fleet Corporation.

When applying for membership in the A.S.M.E. in 1925, Mr. Anderson stated that although he had not taken out any patents he had done considerable design work for changes in vessels under his charge. He mentioned tie bolts for holding brickwork in Foster boilers; improvements in baffles; a time-saving tool for back-facing holes in headers for header plugs; oil burners; oil alarm devices to indicate low lubricating oil in turbine units; and engineroom appliances.

Following his service with the Shipping Board, Mr. Anderson joined the staff of the A. C. Lawrence Leather Co., being attached to its subsidiary, England-Walton & Co., of Hazelwood, N.C., as chief engineer, in charge of six separate plants, and he was holding this position at the time of his death.

Mr. Anderson joined the A.S.M.E. as a member in 1925. He was also a member of the Society of American Military Engineers. In 1921, he married Blanche Oliver, of Parkersburg, W.Va., who survives him.

JAMES DHU ANDREW (1874–1937)

James Dhu Andrew, manager of the American Boiler Manufacturers Association, New York, N.Y., died of pneumonia at his home in Englewood, N.J., on March 22, 1937. Mr. Andrew was born in Brooklyn, N.Y., on October 29, 1874, the son of James D. and Olive (Stevens) Andrew. He attended grammar and high school in Brooklyn, and subsequently spent two years in the School of Mines of Columbia University.

From 1896 to 1899, Mr. Andrew worked as erecting and testing engineer for the Edward P. Allis Company, Milwaukee, Wis. From 1899 to 1902, during the period of its electrification, he served as mechanical engineer for the Metropolitan Street Railway Company, New York, and for the next three years was chief engineer of the New York Edison Company.

In 1907, Mr. Andrew began a term of six years as superintendent of power for the Boston (Mass.) Elevated Railway system, and then spent four years as superintendent of station engineering for the Edison Electric Illuminating Company of Boston. From 1917 to 1920, he was general superintendent of plant construction and manager of hull construction of the American International Shipbuilding Corporation, Hog Island, Pa. During the next three years he was president, first of the American Balsa & Balsa Refrigerator Company, New York, and then of the Standard Tank Car Company, Sharon, Pa. From 1923 to 1926 he was vice-president of Stevens & Wood, Inc., engineers and constructors, New York, in charge of the design, construction, and operation of some power plants in Ohio and Pennsylvania, and also engaged in engineering surveys in South America.

Mr. Andrew acted as general consulting engineer for Armour & Co., of Chicago, Ill., from 1926 to 1929, and then became chief engineer of the Niagara & Hudson Power Corp. In 1933, he was appointed manager of the American Boiler Manufacturers Association and Affiliated Industries, and was thus employed at the time of his death.

In 1904, Mr. Andrew became a member of the A.S.M.E. He was also a member of the American Institute of Electrical Engineers, Society of Naval Architects and Marine Engineers, the Engineers Club, New York, the American Trade Association Executives, Winslow Lewis Lodge, F. & A. M., and Aleppo Shrine in Boston. He served as a member of the Board of Governors of the Englewood Hospital Association.

Mr. Andrew married Laura Ward, of Napanee, Ontario, in 1902, and is survived by her and by their son, James D., Jr., of Essex Fells, N.J.

JESSE OLIVER ARKEBAUER (1871–1937)

Jesse Oliver Arkebauer, marine surveyor and consulting engineer, New York, N.Y., died at the Marine Hospital, on Staten Island, on April 13, 1937, after nearly a year's illness. He is survived by his widow, Ada (Wheeler) Arkebauer, whom he married in 1900, and by a daughter, Gladys.

Mr. Arkebauer was well known in steamship and shipbuilding circles throughout the United States. He held an unlimited license as chief engineer on ocean steamships; had received a certificate of proficiency from the Brooklyn Polytechnic Institute for two years' special training in the design, construction, and operation of Diesel engines;

and was a graduate from the five-year course in general science of Cooper Union, receiving a mechanical engineering degree in 1919. He was commissioned an Engineer Officer in the 2nd Battalion of the New York State Naval Militia in May, 1915, and was retired in September, 1935, with the rank of Lieutenant-Commander in the U.S. Naval Reserve. He had been a member of the A.S.M.E. since 1921, and was also a member of the Society of Naval Architects and Marine Engineers, Propeller Club of the U.S. Port of New York, Marine Square Club of New York, and Port Tampa Lodge, F. & A. M.

Mr. Arkebauer was born at Nokomis, Ill., on September 1, 1871, son of Hye G. and Martha (Peyton) Arkebauer. He went to sea at the age of twelve, working his way up, rank by rank, to the berth of chief engineer, first serving in that capacity on the army transport S.S. *Torpon* in 1898. Later during the Spanish-American War he was assigned to the S.S. *Margarette* and S.S. *Florida*. Subsequent to the war he continued at sea until June, 1905, being first assistant engineer on the S.S. *Havana*, S.S. *Esperanza*, and S.S. *Morro Castle*. Then, after a few months' engineering work in New York, he was made chief engineer of the ferryboat, *Brooklyn*, in 1905. He remained in that service until 1907, when he was appointed assistant inspector of boilers for the United States Steamboat Inspection Service at the Port of New York. He was engaged continuously in this work until April, 1917, with the exception of a few weeks' active service in the New York State Naval Militia earlier that year. From then until November, 1919, he served in the United States Navy as machinery inspector at the New York Navy Yard, Brooklyn. During this period he supervised the fitting out of a large number of submarine chasers, overseas troop ships, and other classes of vessels. For the next nine years he was superintending engineer for Phelps Bros. & Co., New York, the American and Canadian agents for the Cosulich Steamship Line, of Trieste, Italy. Since 1928 he had been engaged in private practice as marine surveyor and consulting engineer.

CARL BENNETT AUEL (1870–1937)

Carl Bennett Auel, manager of the Employees Service Department of the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., died on April 4, 1937, at his home in Irwin, Pa.

Mr. Auel was born in Brooklyn, N.Y., on March 21, 1870, son of Charles and Annie (Lambert) Auel. He attended the Polytechnic Institute of Brooklyn and the School of Engineering of Columbia University, then entered the School of Mechanical Engineering of Cornell University, from which he received the degree of mechanical engineer in 1892. He spent a part of the following year in graduate work, then entered the employ of the Westinghouse company, Pittsburgh, as assistant general foreman. He continued with the company until 1897, being in charge of the Production and Specification Departments during the latter part of the time.

For the next two years Mr. Auel was, first, general manager of the Clark Brake Company, Pittsburgh, then engineer of the Westinghouse Airbrake Company, Wilmerding, Pa. In 1901 he went to Manchester, England, as assistant to the general manager of the British Westinghouse Electric & Manufacturing Co., later becoming assistant general manager. He returned to the United States in 1905, resuming his association with the Westinghouse company here as assistant to the manager of works. Subsequently he became manager of the Railway and Control Departments, then assistant manager of works, director of standards, processes, and materials, and in 1920, manager of the Employees Service and Works Standards Departments. He established the company's building and loan association and tuberculosis sanatorium and developed a medical service for the employees. He was also in charge of the pension system, company restaurants, and Materials Disposition Department.

Mr. Auel had been a member of the A.S.M.E. since 1914. He was chairman of the Sectional Committee on a Safety Code for Mechanical Power Transmission Apparatus from the time of its organization in 1921 until his death, serving as one of the representatives of the A.S.M.E. He was appointed a member of Subcommittee No. 3 on Mechanical Power Control when it was formed in February, 1929, and was elected its chairman, in which capacity he served until the committee was discharged in December, 1935. He was also active in the work of the Management Division of the Society, and particularly in its Management Week campaigns and waste elimination activities; he had been chairman of the Subcommittee on the Elimination of Waste since the time of its organization in 1930, and was instrumental in the compilation and publication of the Waste Materials Dictionary. He was the author of many articles and addresses on industrial relations. Mr. Auel was also a past-president of the National Safety Council (1924–1925), and a member of the Western Pennsylvania Safety Council. He served as president of the Allegheny Public Health Association in 1925–1926 and belonged to the Pennsylvania State and the Pittsburgh Chambers of Commerce, Pennsylvania State Council for the Blind, Pennsylvania State Board of Health, and Philadelphia Board of Trade. He was a member of the Methodist church and Delta Upsilon fraternity, and was a Republican in politics. He enjoyed reading, especially historical works, gardening, camping, and historical and genealogical writing.

Surviving him are his widow, Louisa (Clark) Auel, whom he married in 1901, a son, Carl Clark Auel, and three sisters.

TOM BARKER (1884–1938)

Tom Barker, industrial engineer for the United Parcel Service, New York, N.Y., died on March 14, 1938.

Mr. Barker was born at Baraboo, Wis., on September 26, 1884, the son of John and Alice (Druse) Barker. He prepared for college in the Englewood (Ill.) High School, and then attended Dartmouth College, where he was graduated in 1906 with an A.B. degree.

His first employment, 1906–1908, was with the Western Electric Company in Chicago, Ill., where he took a general shop training course and did considerable clerical work. From 1908 to 1910, he worked for the Rex Tool & Manufacturing Co., Chicago, doing shop work in gasoline engine production, tools and dies. In 1910–1914, he was employed by the Rogers Addresser Company, Chicago, as manager of manufacturing addressing machines. In 1917–1919, Mr. Barker served as First Lieutenant of Infantry, 314th Machine Gun Battalion, 80th Division, A.E.F., in France.

On his return to civilian life, he worked in 1919–1920 in the Hawthorne Plant of the Western Electric Company in the establishment of piece rates, and followed this by a year's employment by Arison Goodwin & Associates, Chicago, consulting industrial engineers. Following this position, Mr. Barker became associated with the United Parcel Service and remained in their employ up to the time of his death.

He joined the A.S.M.E. as an associate-member in 1922, and in 1935 was automatically transferred to the member grade. Mr. Barker married Marie Therese Polet in 1937, and is survived by her and also by two brothers, Ralph and Hugh Barker, also engineers.

BERNARD CLEVELAND BECKER (1887–1938)

Bernard Cleveland Becker, development engineer with The Hoover Company, North Canton, Ohio, died suddenly of a heart attack on March 19, 1938.

Mr. Becker was born on November 16, 1887, in York, Pa., the son of Henry Franklin and Rebecca Jane (Zeigler) Becker. He was educated in public schools and afterwards took the complete course in mechanical engineering as given by the International Correspondence Schools. He began work in 1903 and had four years of practice in general machine shop work and toolmaking. In 1908 he entered the employ of the Heany Laboratories, Inc., New Haven, Conn., where he worked successively for ten years as machinist, draftsman, factory engineer, and chief engineer, occupying the last position for eight years.

For the year 1919, Mr. Becker was employed by the Tabulating Machine Company, Endicott, N.Y., as machine designer. In 1920 he began private practice as patent attorney at York, Pa., and carried on this work until 1926, though in 1924 he became associated with the York Manufacturing Company in the development and design of refrigerating machinery.

In 1927, Mr. Becker was engaged by The Hoover Company of North Canton, Ohio, "to create, improve, and develop mechanical and electrical devices." The company wrote that his ten years of service was marked by many successful achievements in the creative-inventive field and his work was outstanding. His attack on a problem was thorough and from many angles, which usually resulted in a number of designs from which a choice could be made. His layout work was clear, concise, and well planned, making it easy to interpret in the model construction department." Mr. Becker also invented a suction cleaner and several mechanical lead pencils.

Mr. Becker married Bernice E. Deardorff in 1926, and is survived by her and by two sons, Charles H., of Orange, Texas, and Ned G., of Lawton, Okla., as well as by his mother.

He became a member of the A.S.M.E. in 1932. He was also a member of Federal Lodge No. 1, F. & A. M., Capital Chapter, R.A.M. and Washington Commandery No. 1, Knights Templar, Washington, D.C., and of the Elks Club, of Flint, Mich.

HENRY LÉON BANCEL BINSSE (1852–1938)

Henry Léon Bancel Binsse, of Washington, D.C., died at his summer home at Pointe au Pic, County Charlevoix, Que., Can., on July 2, 1938. He was born in New York, N.Y., on November 14, 1852, son of Louis Bancel and Mary Delia (Carpenter) Binsse, and was de-

scended from the French families of Binsse de Saint Victor and Bancel, who came to New York at the time of the French Revolution. His early education included a period of engineering study at Düsseldorf, Germany.

When Mr. Binsse applied for membership in the A.S.M.E. in 1882 he submitted the following record: "Following my graduation with the degree of C.E. from Rensselaer Polytechnic Institute, Troy, N.Y., in 1875, I took a position at the North Chicago Rolling Mill, Chicago, Ill. I found that my taste led me to mechanical engineering and I, consequently, entered the works of C. H. Delamater & Co., New York, and familiarized myself with the trade. In 1879, I entered the firm of George A. Ohl & Co., engineers and machinists, of East Newark, N.J., of which firm I am still an active member." He made improvements in small turning lathes and horizontal boring machines while with this company.

In 1887 he established his own business, the Newark Machine Tool Works, in Newark, and he continued the manufacture of machine tools under that name until 1902 and as president of the Binsse Machine Company, Newark, from then until his retirement in 1914. He took out a patent on a screw-jack in 1883, one on a slotting machine in 1889, and one on gearing in 1899.

Mr. Binsse married Elizabeth Hewlett Scudder on November 10, 1903, and is survived by her and a son, Harry Lorin Binsse, residents of Washington, D.C., and Glen Cove, L.I., N.Y., respectively; also by a sister, Alice (Mrs. Schuyler N. Warren), of New York, N.Y.

He resigned his membership in the A.S.M.E. in 1911 but was reinstated as of 1882 by action of the Council in 1917, with permanent remission of dues.

WOODROW W. BLACK (1912–1938)

Woodrow W. Black, an employee of the Reid Diesel Engine Company, of Oil City, Pa., died on August 2, 1938, of colitis, in the General Hospital, Buffalo, N.Y.

Mr. Black was born on January 21, 1912, at Cyril, Okla., the son of Warner and Annie Caroline (Williams) Black. He was graduated from the University of Oklahoma in June, 1937, with a B.S. degree, and had been in the employ of the Reid Diesel Engine Company since that time.

He became a junior member of the A.S.M.E. in 1938, and was unmarried.

EDMUND E. BLAKE (1870–1938)

Edmund E. Blake, chief engineer of Saco-Lowell Shops, Biddeford, Maine, died in Portland, Maine, on June 21, 1938, following a major operation.

Mr. Blake was born in Boston, Mass., on November 13, 1870, the son of James M. and Mary H. (Brown) Blake. He prepared for college in the Newton High School, Newton, Mass., and was graduated in 1893 from the Massachusetts Institute of Technology with an B.S. degree in mechanical engineering.

Mr. Blake's entire business career was devoted to Saco-Lowell Shops and its predecessors. Following his graduation, he served a year's apprenticeship in the shops of the Pettee Machine Works, Newton Upper Falls, Mass., and continued with that company until 1897, when he was in charge of machinery installations. He was associated with H. S. Chadwick, textile and mill engineer, in 1897–1899. He then took the position of salesman and engineer for the Saco and Pettee Machine Shops and in 1904 became manager of the Saco-Pettee Company at Biddeford. He was appointed chief engineer of Saco-Lowell Shops in 1923, and was responsible for many valuable improvements and inventions in cotton-mill machinery, the most notable being the commercial development of long-draft processing which has revolutionized the cotton-spinning industry in the last decade. He lived across the river in Saco, Maine, and was a valued member of the community, serving it in many capacities for 34 years.

Mr. Blake became a member of the A.S.M.E. in 1913. In 1896, he married Clara S. Sheppard, of Newton, Mass., and they had two sons, Malcolm S. and Edmund G., and a daughter, Mary, all married, and all of whom, together with six grandchildren, survive him.

HARVEY BOLTWOOD (1875–1938)

Harvey Boltwood, director of the Bureau of Service of the Interstate Commerce Commission, Washington, D.C., died suddenly of a coronary occlusion on September 2, 1938, while on the way to his office.

Mr. Boltwood was born at Albany, N.Y., on July 6, 1875, the son of Ransom Haight and Sarah Effie (Clarkson) Boltwood. He moved to Denver with his parents in 1888 and completed his preliminary education in the public schools there. He then worked for two years with the Union Pacific Railroad in Denver, after which he spent a year at Colorado College, Colorado Springs. His studies there were supplemented later by correspondence courses through the International Correspondence Schools.

In 1899, Mr. Boltwood began four years' service as machinist in railroad, mine, and mill work in Colorado, Idaho, and Washington. From 1903 to 1907, he was supervising locomotive construction and maintenance for the Denver & Rio Grande R.R. in New Mexico and Colorado. The next three years Mr. Boltwood spent in cyanide mill construction and operation in Colorado, as master mechanic. He gave this up in 1910 and was employed for the following year in charge of enginehouse and locomotive maintenance for the Union Pacific Railroad at Denver.

Mr. Boltwood's first service with the Interstate Commerce Commission began in Washington in 1911 when the Bureau of Locomotive Inspection was organized. He was one of the original fifty district inspectors. In 1918, he was transferred to the Division of Operation of the U.S. Railroad Administration as supervisor of equipment. In this connection he was sent to many points to make surveys of plant layouts and equipment with a view to initiating changes to increase output. He had some part in the design of standardized equipment at that time and later made a study of criticisms of it for the Department of Equipment, Division of Liquidation Claims. He was appointed mechanical engineer for this department in 1920, when the railroads were returned to private operation, his duties relating chiefly to handling engineering features in connection with the settlement of claims against the Railroad Administration. In 1922–1923 he was engaged in commercial education work in Colorado, and then he returned to the Interstate Commerce Commission, and was stationed at Shreveport, La., in the Bureau of Locomotive Inspection.

In April, 1925, Mr. Boltwood was appointed assistant director, Bureau of Service, for the Interstate Commerce Commission, in charge of the Section on Efficiency and Economy of Operation. He also was consultant in matters relating to the design of containers for shipping explosives and other dangerous items, particularly tank cars. In March, 1937, he was made director of the Bureau of Service, the position he was filling at the time of his death.

Mr. Boltwood joined the A.S.M.E. as an associate-member in 1921, and was promoted to member in 1930. He was also a member of the Mechanical Division of the American Railway Association, the International Association of Machinists, the Sons of the American Revolution, and the Masonic order. He was a member of the Galilee Baptist Church in Denver for many years and belonged to the National Baptist Memorial Church in Washington. In the A.S.M.E., Mr. Boltwood served on the Executive Committee of the Washington, D.C., Section from 1929 to 1932, as its chairman the last year. He was a member of the Section's Subcommittee on the Economic Status of the Engineer in 1928. He was also appointed a member of the General Committee (RR 2) of the Railroad Division in 1937, for the term 1937–1939. During 1937, he was also a member of a committee appointed by the District of Columbia Council of Engineering and Architectural Societies to study and report upon proposals looking toward the enactment of a law covering the practice of these professions in the District.

In 1917, Mr. Boltwood married Maude Margaret Morgan, who survived him, and they had two children, both living: Ransom Harvey and Charlotte Boltwood.

HENRY EDWARD BRETT (1858–1937)

Henry Edward Brett, consulting engineer, of Los Angeles, Calif., died at his home in that city on April 3, 1937. Mr. Brett was born in British Guiana, South America, on November 13, 1858, the son of Rev. William H. Brett and Caroline Brett. He was educated in the Grammar School of Loughborough, England, and by private tuition. He then spent some six years as apprentice in engineering works, covering patternmaking, machine shop, and millwright work, and as student draftsman with W. H. Thornbery, consulting engineer, of Birmingham, England.

He arrived in the United States in September, 1880, and spent four years as draftsman with E. D. Leavitt, Jr., Cambridgeport, Mass.; I. P. Morris Co., Philadelphia, Pa.; Robert Wetherill & Co., Chester, Pa.; and the Scott Foundry, Reading, Pa. He then went to the West Coast, where he served with the Pacific Rolling Mill Company of San Francisco, as draftsman, engineer in charge of the construction of cable railways in San Francisco and Oakland, and assistant to superintendent in charge of steel works. In 1887 he returned to the I. P. Morris Co., in Philadelphia, as draftsman, and subsequently was with Wm. Wharton Jr. & Co., Inc., of that city, as draftsman and designer of special machinery. Then, in 1890, he went back to the West Coast and joined the staff of the Pacific Rolling Mill Com-

pany, serving as constructing engineer for the Los Angeles Consolidated Electric Railway, of Los Angeles, where he was in full charge of track work, design and construction of powerhouse, and installation of steam and electric equipment and rolling stock. From 1892 to 1893, he held a similar position with the San Diego Electric Railway, of San Diego, Calif., and next served for one year with the Baker Iron Works, of Los Angeles, as mechanical engineer.

From 1894 up to his death, Mr. Brett practiced as consulting mechanical engineer in Los Angeles. His work covered general practice: machine design, development of inventions, structural work, and investigations and reports. Among other things he designed machinery for can making and canning equipment, machines for flax treatment, pressure filters, excavators, and shipyard machinery.

Mr. Brett obtained a number of patents, including oil burners, crematory furnaces, a continuous pressure cooker, and various machines for special purposes. In 1905 he served as a member of the Commission to Investigate the Construction of an outfall sewer for the City of Los Angeles. He was a registered civil engineer, State of California. He joined the A.S.M.E. as a member in 1902 and served on the Executive Committee of the Los Angeles Section in 1921–1922 and 1928. He was at one time a member of the Engineers' and Architects' Association for Southern California and had taught mechanical drawing in the Y.M.C.A. of Los Angeles.

On November 25, 1885, Mr. Brett married Miss Emilie T. Bridle, of Philadelphia, and they had three sons: H. Austin, born December 29, 1887; Edward C. N., born June 9, 1892; and Arthur T., born February 10, 1894. He became a citizen of the United States by naturalization in Los Angeles, 1896.

BENNETT MATTINGLY BRIGMAN (1881–1938)

Bennett Mattingly Brigman, best known as organizer and first dean of the Speed Scientific School of the University of Louisville—Ben to a host of personal friends—was a true Kentuckian. Born in Louisville, on February 25, 1881, the son of William Frederick and Margaret (Lehman) Brigman, he was long active in the professional and educational activities of state and city and died in Louisville, February 8, 1938. Mrs. Brigman, the former Alice Jessel, of Louisville, whom he married in 1904, survived him.

He attended the Universities of Kentucky and Louisville, receiving the degrees of B.S. and M.S. from the latter, in 1908 and 1912, respectively, and did special graduate work at the University of Wisconsin in the summer of 1915. He engaged in practical engineering for a number of years, principally in the shops, engineering offices, and test plants of the Louisville & Nashville Railroad. Long interested in boys, he left this work to organize and direct their pre-college and vocational training, first in the Manual Training Department of the University School, a one-time private preparatory school in Louisville, and then in the DuPont Manual Training High School of Louisville. From there he went to the University of Louisville as instructor in physics, later becoming professor of engineering and drawing.

Thus by broad training and by natural interest, he was well qualified to undertake the planning, building, and initial operation in 1924 of the Speed Scientific School, for which he served as inspiration as well as administrative head until his death. It was on the basis of his prospectus that gifts were made by William S. Speed and Mrs. Olive (Speed) Sackett to establish the James Breckenridge Speed Foundation. He served as guiding architect and dean of this, the first southern school to be accredited in all its branches of engineering, until his death.

He contributed much to his native city and to his native state. But it is as a nationally known engineer and personality, well acquainted throughout this country, that most of us knew him—as a leader in the Council of National Defense and in the Bureau of War Savings Stamps during the World War—as an authority on zoning and planning, municipal and community, and on smoke abatement—as a member and participant in many national projects of educational and professional nature—as a member and officer of national educational and engineering associations, particularly as vice-president of The American Society of Mechanical Engineers and of the Society for the Promotion of Engineering Education.

He became a member of the A.S.M.E. in 1923 and one of its Fellows in 1936. He served as chairman of its Louisville Local Section, 1925–1934; as a member of the Special Committee on Policies and Budget, 1933–1936; as a delegate to the American Engineering Council, 1933–1935; and as a manager of the Society, 1934–1937, and vice-president from then until his death.

These are the formal activities and accomplishments for which Dean Brigman will long be remembered—but those who knew him well personally, who sat on Council or Committee with him, in conversation with him in his home, or beside him during long train rides to conferences, or who joined his ever-present group of friends at conventions, will prefer to remember certain distinctive personal traits. There was his ever-impelling interest in his fellowmen, particularly his fellow students, whose ranks he never left—his never-failing infectious sense of humor, which made him take his job, but not himself, seriously—his unbounded enthusiasm and industry, despite a relatively weak physique—his sheer likableness as a man, as a teacher, and as an engineer.

These are the characteristics that made Ben Brigman stand well above his fellows.—[Memorial prepared by EUGENE W. O'BRIEN, Atlanta, Ga., Past Vice-President, A.S.M.E.]

MORTIMER COWPERTHWAITE BROWN (1887–1938)

Mortimer Cowperthwaite Brown, whose death occurred at his home in Mount Vernon, N.Y., on August 20, 1938, was born there on November 5, 1887, son of Edgar K. and Emily (Cowperthwaite) Brown. He prepared for college in the Mount Vernon schools and was graduated from Stevens Institute of Technology as a mechanical engineer in 1910. During the next eighteen months he was employed by the Russell, Burdsall & Ward Bolt & Nut Co., Port Chester, N.Y., as assistant to the foreman of the machine shop, and by the Max Ams Machine Company, Bridgeport, Conn., in drafting work on automatic machinery. He then became draftsman for the Hodgman Rubber Company, Tuckahoe, N.Y., with which he remained until the fall of 1914, being promoted during that time to chief draftsman and then second assistant chief engineer.

Beginning in January, 1915, Mr. Brown was connected for about four years with the Aetna Explosives Company, serving at first as draftsman and inspector at New York, and later as chief engineer at the Fayville, Ill., plant of the company. He returned to New York in 1919 as mechanical engineer for the Pratt Engineering & Machine Co., with which he continued until April, 1921.

His next employment of note was with the Western Electric Company, New York, for three years beginning in May, 1925. During the following year he was an estimator for Coverdale & Colpitts, consulting engineers, New York, in connection with a project covering the cost and valuation of the Interborough Rapid Transit Company. Subsequently he was engaged in layout and drafting for the American Cyanamid Company, General Chemical Company, and John Johnson Sales Corporation, in New York. He was senior engineer and valuation checker for Maurice R. Scharff, consulting engineer, New York, September, 1934, through February, 1935, and from April to October of that year was engaged in making an inventory of gas plants and pumping stations for the Consolidated Gas Company, New York. He then was employed by the Law Department of the City of New York as valuation engineer on the appraisement for tax purposes of public utility power plant and substation machinery and equipment. He was transferred to the Tax Department at the beginning of 1936, and employed there until the end of the year and again from March, 1937, to February, 1938, when all engineers engaged on this work were released, later to be replaced by civil service engineers. During the spring of 1938 he was a provisional assistant electrical engineer for the New York Board of Transportation, in connection with listing and pricing equipment on elevated lines.

Mr. Brown became an associate-member of the A.S.M.E. in 1915 and was automatically transferred to full membership in 1925. His wife, Ethel (Stickney) Brown, whom he married in 1917, survives him.

ARTHUR BRUCKNER (1872–1937)

Arthur Bruckner, professor and head of the department of mechanical engineering in the School of Technology of the College of the City of New York, died of a heart attack on August 29, 1937, at his home in Hastings-on-Hudson, N.Y. He had been on leave of absence from the college since February because of ill health.

Professor Bruckner was born in New York on April 22, 1872, the son of Herman and Susan (Hoffman) Bruckner. His preparatory education was obtained in the New York public schools. He was graduated with a B.S. degree from the College of the City of New York in 1892, and in 1898 from the Sibley College of Cornell University, with an M.E. degree. He later took one year of graduate work in Cornell University, and three years of evening work in the New York Trade Schools.

From 1892 to 1897, Mr. Bruckner taught mechanic arts in the College of the City of New York. The next two years he spent at Cornell for his M.E. degree and graduate work. From 1899 to 1904, he was instructor in physics and the mechanic arts at the College of the City of New York, and organized the work of laboratory instruction in physics. In the years 1904–1907, he was busy in the planning, construction, and equipment of the Mechanic Arts Building of the College of the City of New York. He personally designed much of

the equipment for the laboratories and supervised its installation, and served as instructor in the mechanic arts and in the mechanical laboratory.

In 1907, Mr. Bruckner was made director of the Mechanic Arts Laboratories and instructor in various mechanical engineering subjects. In 1917 he was appointed assistant professor of mechanical engineering. He advanced to the rank of associate professor at the beginning of 1929, and was appointed full professor of mechanical engineering, in charge of the department, on January 1, 1936.

Professor Bruckner became a member of the A.S.M.E. in 1919. He was also a member of the Society for the Promotion of Engineering Education and the American Association of University Professors. He was much interested in education in general, and at the time of his death was serving his second term as trustee of the Union Free School District No. 4, Town of Greenburgh, Westchester County, N.Y. He had long made his home in Hastings-on-Hudson, N.Y., where he had served as a member of the Hastings Board of Education since 1935, and a member of the Hastings Taxpayers Association, and was both a member and secretary of the original Riverview Manor Association.

In September, 1898, Professor Bruckner married Mabel C. Earll, of Ithaca. He married a second time, in December, 1906, Ella May Ford, of Washington, D.C., who survives him. Surviving also are a son, Robert Earll, of Vineland, N.J., and three daughters, Mrs. Mabel Amelia Chomsland, of Ridgefield Park, N.J., and Mrs. Helen Sue Fagans and Mrs. Virginia Ford von Isecke, of Basking Ridge, N.J. He also left a sister, Mrs. Annie Hillenbrand, of New York.

EDWIN BURHORN (1866–1937)

Edwin Burhorn, president of the Edwin Burhorn Company, of Hoboken, N.J., died in Margaretville, N.Y., on September 26, 1937, after a brief illness. A sister, Miss Etta Burhorn, and a son, Alfred Burhorn, survived him. He had been a member of the A.S.M.E. since 1914.

Mr. Burhorn was graduated from the Stevens Institute of Technology in 1885, with a degree in mechanical engineering. The Morton Memorial volume published by the Institute in 1905 contains the following biography of Mr. Burhorn.

"Edwin Burhorn was born in New York, June 21, 1866, the son of August and Henrietta W. Bickel Burhorn. Both parents were born in Germany and came to the United States about 1849, their parents being revolutionary exiles. He was educated in the public schools of Hoboken, N.J., graduating from Hoboken High School and receiving the Stevens scholarship. He served as draughtsman with Henry Warden, Germantown Junction, Philadelphia, Pa., manufacturer of boilers and special wrought-iron work, etc., 1885; and as assistant to the general manager of the Franklin Sugar Refinery, Philadelphia, 1885. While in the latter position he took entire charge of testing boilers, engines, evaporating apparatus, etc., designed and installed a special system of draining bag filters by vacuum process, filling char filters by automatic spreading-machines, etc. He became interested with Mr. B. H. Coffey, '85 (Stevens Institute), in the Cycle Water Filter, having obtained a patent on a special controlling valve mechanism, and joined with Mr. Coffey at the shops of Henry Warden, improving the filter and placing it successfully on the market. He was with the Link-Belt Engineering Co., of Philadelphia and New York, 1890–1893, planning many systems of handling material by machinery of special design, and afterward took entire charge of the designing department of the New York office of the same company.

"In 1893 he started in business as an engineer and contractor under the firm name of Warren & Burhorn, changed the following year to Burhorn & Granger,* of New York, the firm acting as manufacturers' agents in addition to professional work. This partnership lasted for eight years, during which time it installed many complete plants for power, heat, and electric light; made several improvements in the Woodbury high-speed automatic engine, built by the Stearns Manufacturing Co., and placed the engine in successful operation in many places, notably in the *World* Building, New York. In 1901 the firm of Burhorn & Granger was dissolved, Mr. Burhorn opening an office for himself in New York, as engineer and contractor, which business he is now carrying on. Some of the installations made under Mr. Burhorn's supervision are as follows: Boiler plant at the rope-walks of the Boston Navy Yard (750 horsepower); electrical transmission plant for the factory of John Mehl & Co., Jersey City Heights; a motor-driven swing-bridge over the Passaic River, at Fourth Avenue, Newark, N.J.; char-drying equipment and incinerator for sugar-baskets at the Arbuckle sugar-refinery, Brooklyn, N.Y., and an Acme water-cooling tower at Baltimore, Md. . . . showing a class of work of which Mr. Burhorn is making a specialty,—namely, recooling water from condensers in steam plants, or, in ice plants, for recooling water from ammonia condensers. He is a member of The Franklin Institute of Philadelphia."

About the year 1905, cooling towers were designed with perforated pans for the cooling surface and with wire mesh placed on the outside of the tower to act as louvers to prevent the water from being blown away by the wind. Up to the time of his death in 1937, Mr. Burhorn had been granted more than fifty patents on cooling towers and auxiliary apparatus. Some of these developments include all-steel and all-wood construction, the narrow-type tower, indoor-type installation, forced-draft tower, louver fence, and many others for use with refrigerating machines, Diesel engines, air compressors, oil-refining equipment, and air-conditioning apparatus. Burhorn cooling towers are found in all parts of the world and in almost every state in this country, in use by manufacturers, food industries, breweries, meat packers, dairies, and ice plants.

In June, 1910, Mr. Burhorn incorporated his company and was president and chairman of the board until his death. Because of the individual requirements of each cooling-tower installation, the Edwin Burhorn Company, engineers, contractors, and manufacturers, carries through a design from the beginning to the final erection. Other equipment manufactured by the company includes spray-pond apparatus.

* For biography of Abbott D. Granger, see page RI-55.

JOHN ALLEN CAPP (1870–1938)

John Allen Capp died on January 6, 1938, at the age of 68 years. He was born in Philadelphia, Pa., on January 14, 1870, and received his education at the Central High School (where Prof. Elihu Thomson was, at that period, associated with the science courses), and at the University of Pennsylvania. In 1892 Capp was engaged by the Thomson Houston Electric Company in the mechanical testing laboratory at the company's West Lynn Works. That laboratory and two other laboratories, dedicated respectively to chemical and electrical testing and investigations, were located in a very large basement, below the office building. The equipment of the three laboratories was remarkably complete, considering the state of advancement in science and engineering at that early period.

Today such an assemblage of apparatus, machinery, and personnel would be termed a research laboratory. It is probable that, at that time, no finer testing facilities in the field of general engineering and scientific research had ever been provided by any manufacturing corporation in this country. E. W. Rice, Elihu Thomson, and A. L. Rohrer, who had collaborated in the design of this laboratory, were justly very proud of it and they brought down from the offices many visitors from all over the world. Everything was shown to the visitors without any reservation whatsoever. Incidentally it served as a fine inspiration to the personnel to meet so many distinguished pioneering scientists and engineers.

Capp's assignments related chiefly to materials, especially to metals and insulation. In those early days, relatively little was known concerning the properties and characteristics of materials used in the manufacture of electrical equipment and products. Much remained to be learned. In the course of his professional career of 45 years, Capp contributed a very noteworthy share of the knowledge of these materials, which have since been developed, and he aided greatly in improving them to their present high quality. In 1892, cast steel was just emerging as a rival to cast iron and wrought iron for generators, railway motors, and other electrical apparatus. (Outside of railway motors, there was at that time no quantity production of electric motors for other than extremely small powers.) The kind of sheet iron available for armature cores and for transformers not only had a high hysteresis loss, but this loss increased rapidly with time in service. However, in conformance with common experience, since we had no knowledge that core material several times better ever would be developed, most people concerned were fairly contented. Few of the faults in insulating materials had yet been overcome; indeed they scarcely were realized. The quality of the oil used in transformers left much to be desired, and the nature of its faults already was being vigorously investigated. The investigations are continuing today, almost half a century later.

In May, 1894, after the Thomson Houston Company and the Edison Machine Company had been consolidated as the General Electric Company, Capp was transferred to the Schenectady Works. In 1896 he was placed in charge of the Materials Testing Laboratory. In this capacity Capp had the responsibility for the preparation of specifications for all materials purchased by the company and for their inspection and testing. In parallel with these duties Capp was constantly carrying on special experimental work and researches on materials and apparatus. Along with other materials, coal was an important item in the list of Capp's responsibilities and early received his active attention. At first, the coal people resented the in-

trusion of specifications concerning their "natural" product, but soon they became impressed by Capp's fairness and they accepted the methods he proposed for sampling and for testing the ash and sulphur content and the calorific value. The major burden of these expanding activities was borne by Capp up to 1927, when his laboratory was merged in the new Schenectady Works Laboratory, in which Capp became engineer of materials and continued in that position for the remaining 11 years of his life.

Throughout his professional career, Capp was a very active member of several engineering societies, notably The American Society of Mechanical Engineers, of which he became a member in 1901, and the American Society for Testing Materials, which he served as president for the 1919–1920 term. Honorary membership in that society was conferred on him in 1937. Many technical papers were contributed by Capp in the course of his professional career, not only to these societies but also to the American Institute of Mining and Metallurgical Engineers, the British Iron and Steel Institute, and the Institute of Metals.

In 1919 Capp was appointed one of a group of three representatives of the A.S.T.M. to develop, in collaboration with representatives from other societies, the plans for organizing an American Engineering Standards Committee. Capp entered upon this task with high enthusiasm. The early steps were beset with tremendous difficulties and it was due in no small measure to Capp's sound judgment and organizing experience and ability that finally there emerged from those early efforts the highly successful American Standards Association of today. Dr. Agnew, who has been its secretary from almost the very beginning, has spoken in the highest terms of Capp's valuable contributions to its successful evolution at various critical stages.

Cloyd M. Chapman, who also had much to do with the ASA, writes: "My impressions of Capp concerned chiefly his clear, distinct, precise thinking and the exactness he displayed in expressing his ideas. He hewed to a line and was definite in his ideas. He decided quickly and was slow to change or modify a decision once made. He seldom needed to. I have enjoyed some lovely arguments with Capp even though I often came off second best."

While the ASA achievement probably is the one of greatest consequence in the committee field of Capp's activities, mention certainly should also be made of much other fine committee work contributed by him. Altogether, as a member of the A.S.T.M. since its founding in 1898, Capp served on 18 different committees. Beginning with the establishment of the Committee on Copper and Copper Alloy Wires in 1909, Capp was its chairman, and his expert knowledge of testing methods for determining the properties of nonferrous wire products contributed to the development of specifications and practices which were for years the standards of the copper industry. Also as an active member of the Committee on Steel, Capp headed up various subcommittees and served as chairman of the committee in 1918. From 1920 to 1927 he gave much effort to the reorganization of the Committee on Methods of Testing and served as its chairman until 1927. As a member of the A.S.M.E., he served on the Research Committee Subcommittee on Bearing Metals (later called the Special Research Committee on Bearing Metals), from the time of its appointment in August, 1916, for the study of microstructure and hardness of bearing crystals, until its discharge in December, 1927.

A. L. Rohrer calls attention to the high opinion of Capp's abilities held by Dr. Chas. B. Dudley in the early years of this century. Dr. Dudley was a great pioneer and authority in the field of materials specifications and testing, particularly as relating to steel rails and similar materials. He acted as Capp's mentor on many occasions and visits were frequently exchanged between himself and Capp at Altoona and Schenectady.

G. H. Wright (who was Capp's close associate for many years, including the period of the Schenectady activities) and A. L. Rohrer, recall that, around 1920, Capp did some early testing which led to the substitution of stainless steel for the monel metal buckets in the first stages of his company's steam turbines. With time and experience, this practice was extended through the entire stages. Since the last few stages require strength beyond the range of monel metal, stainless steel buckets replaced 3½ per cent nickel steel. Capp is believed to have been the first to suggest this substitution and he worked very hard for its adoption.

In addition to his engineering interests, Capp took great delight in music. He was one of the founders of the Schenectady Civic Music Association and served as its president from 1932 to 1934. Dr. Felix Kleeberg (who was Capp's chief for some time, in the laboratory work in the 1894–1895 period) in reminiscencing about those early times, speaks of a trio which frequently met and played the classical Haydn trios, Capp playing the piano, a mutual friend (Frank Holden) the cello, and Kleeberg the violin.

There are but few now living who were associated professionally with Capp when he went to work at Lynn at 21 years of age. J. M. Darke, of the Lynn Works of the General Electric Company, referring to that early time, states that they all considered Capp as "a very efficient man, very methodical in his work, and very original in such work." A review of his accomplishments in later life more than justified these impressions of his early associates.

A fitting conclusion to this memorial has been furnished by F. M. Farmer, long associated with him in committee work, who writes: "John Allen Capp leaves with a wide circle of friends and acquaintances the memory of a man who could be depended upon to conscientiously carry out any assignment he accepted, a man whose integrity was never questioned and who would strenuously contend for what he believed to be the right decision, a man whose sound advice was widely sought and was always freely given."—[Memorial prepared by HENRY M. HOBART, Schenectady, N.Y., Mem. A.S.M.E.]

JAMES ADAMS CHARTER (1865–1937)

James Adams Charter, a member of the A.S.M.E. since 1899, died on April 21, 1937. He was born in Sterling, Ill., on July 24, 1865, the son of John and Rachel (Adams) Charter. His public school education was supplemented by studies under a private tutor and an apprenticeship in designing and mechanical work with the Williams & Orton Manufacturing Co., of Sterling. Following the completion of his apprenticeship in 1883 he worked as a draftsman for this company and for H. W. Caldwell & Co., of Chicago, for which he later became general superintendent. Other early connections were with the Sterling Gas Company and the Sterling Gas & Electric Light Co.

Mr. Charter was associated with his father in the design of gas engines, the first patents on which were taken out in 1882. He later described the invention as "the first internal-combustion engine to use liquid fuel (gasoline) injected directly into the suction intake of the engine (now called the carburetor)," and stated that their designs "made it possible to adopt gasoline for powering both automobiles and aeroplanes using internal-combustion engines." From 1894 to 1908 he was connected with Fairbanks, Morse & Co., Beloit, Wis., in charge of the manufacture of these engines, also representing this company in Europe for some time, and during the next four years he was with the Austin Manufacturing Company, Harvey, Ill., as designing engineer in connection with the manufacture of gasoline-driven road rollers.

In 1910 Mr. Charter became president of the Charter Single Sleeve Motor Company, Chicago, developing the rotary-sleeve type of engine for automobiles and aeroplanes. In 1923 he invented a new type engine starter drive, and incorporated a company for its manufacture, Charter Drive, Inc., Chicago, of which he served as president until his death.

Mr. Charter married Miss Julia Wheeler, of Chicago, in 1913, and is survived by her.

LAWRENCE RIPLEY CLAPP (1886–1937)

Lawrence Ripley Clapp, vice-president, The New Haven Copper Company, Seymour, Conn., died on July 9, 1937. He was born on February 25, 1886, in Brooklyn, N.Y., the son of William Gamwell and Sarah Louise (Ripley) Clapp. He prepared for college in the Morristown High School, Morristown, N.J., and was professionally educated at Columbia University, where he was graduated with an M.E. degree in 1910. As a student at Columbia he was awarded the Illig Medal for his outstanding work in metallurgy and was made a member of the honorary societies of Tau Beta Pi and Sigma Xi. Later, besides becoming a member of the A.S.M.E. in 1921, he also joined the American Institute of Mining and Metallurgical Engineers and the Canadian Institute of Mining and Metallurgy, and was a licensed and registered engineer in British Columbia.

From 1905 to 1907, prior to his graduation from Columbia, Mr. Clapp served as assayer, surveyor, miner, and millman at various mines in the United States and Mexico, for the Cananea Copper Company, Federal Lead Company, and Ms. Tecolotes y Anexas. From the time of his graduation in 1910 until the World War in 1917, he served as superintendent, Loreto Mill (silver), Cia de Real del Monte, Pachuca, Mexico; Silver Lake Mines (silver, lead, gold, copper), Silverton, Colo.; Sunnyside Mill (silver, lead, zinc), Eureka, Colo.

When the United States entered the World War, Mr. Clapp became associated with the U.S. Fuel Administration, Washington, D.C., as chief of States Conservation Section; U.S. Army, New York District Ordnance Claims Board, New York, N.Y., general assistant; and until 1922 he practiced as a consulting engineer in plant management and valuation in New York, N.Y.

Returning to the mining business in 1922 he served as assistant general manager, Granby Consolidated Mining, Smelting & Power Co., Anyox and Copper Mountain, B.C.; and in 1924 he returned to this country as vice-president and general manager, The New Haven

Copper Company, Seymour, Conn., the position he held at the time of his death.

Mr. Clapp stated that he had contributed "occasional papers in the technical press;" considered himself "best qualified for the mining and metallurgy of copper, including rolling-mill practice;" and had taken out "several patents on the rolling of copper and other ductile metals."

On April 17, 1915, Mr. Clapp married Miss Helen Tilge, of Philadelphia, Pa., and they had two children: Eleanor Lawrence and Marjorie Ripley.

ERIC HERBERT COSTER (1867–1937)

Several of the more important railroad power plants in this country, together with some private plants, bear testimony to the skill of Eric Herbert Coster, engineer of mechanical design for the Interborough Rapid Transit Company, New York, N.Y., from 1924 until his death in 1937.

Mr. Coster was born in London, England, on June 9, 1867, the son of Fredrick Leonard and Elizabeth (Bradley) Coster, but went to Sweden at an early age. He received his preparatory education at the grammar school in Uddevalla, Sweden, and the high school in Gothenburg, Sweden, and then attended the Chalmers College of Engineering, Gothenburg, receiving his diploma on his twenty-first birthday. Beginning in March, 1889, he worked for eighteen months as a fitter and erecting engineer on steam fire engines and pumping machinery for the Ludwigsberg Engineering Company, Stockholm. From then until May, 1896, when he came to this country, Mr. Coster was superintendent of his father's woodworking plant and planing and sawmills at Uddevalla.

His first employment after coming to the United States was with Sheaff & Jaastad, consulting engineers, Boston, Mass., as a draftsman on general plans and details for powerhouses and equipment. In April, 1897, he went with the Boston Elevated Railway Company, where he was engaged until December, 1898, in drafting and field work on powerhouse equipment, especially piping, and in the operation of two powerhouses. A brief engagement as a draftsman on piping with the New England Gas & Coke Co., Boston, followed, and, in March, 1899, Mr. Coster began an association with Westinghouse, Church, Kerr & Co., New York, N.Y., which lasted, with a single brief interruption, for fifteen years.

Drafting on building and equipment plans and details for the Kingsbridge powerhouse at New York and other powerhouses was Mr. Coster's first work with Westinghouse, Church, Kerr & Co. and was interrupted early in 1901, when he went to the London office of the British Westinghouse Electric & Manufacturing Co. to design a power plant for the Mersey Railway Company, at Birkenhead, and the Neasden power plant for the Metropolitan Railway, London. He returned to the United States late in 1902 and resumed work for Westinghouse, Church, Kerr & Co. as an assistant engineer, being subsequently promoted to the position of engineer-in-charge. Some of the more important work with which he was associated for the company included the design of five electrical substations for the Long Island Railroad and inspection of field work in this connection; general design of the power plant for the Congressional Office Buildings at Washington, D.C.; general design of the Cos Cob, Conn., power plant of the New York, New Haven & Hartford R.R., and arrangement of equipment; design and equipment of the Waterbury power plant for the Connecticut Company; design of producer-gas and gas-engine plants for the Harriman Estate at Harriman, N.Y., and purchase of all equipment, and supervision of field work in connection with this plant; similar work in connection with a mechanical-stoker and forced-draft installation at the Chicago plant of the N. K. Fairbank Company; and design and construction of an extension to the plant of the Fall River (Mass.) Electric Light Company. During these years Mr. Coster also did some appraisal work in connection with power plants.

From 1915 to 1917 he was engaged in the design and construction of new power plants and extensions to existing power plants for E. I. du Pont de Nemours & Co., Wilmington, Del. This employment was followed by work with Gibbs & Hill, consulting engineers, New York, in connection with the proposed improvement of the Pennsylvania Railroad Station at Pittsburgh, from June, 1917, to July, 1918. From then to February, 1920, he was engineer-in-charge for Henry R. Kent & Co., engineers and constructors, New York. The following April he took a position as assistant mechanical engineer with The Foundation Company, New York, with which he remained until May, 1921. About a year later he was appointed assistant appraisal engineer with the Board of Public Utility Commissioners, State of New Jersey, where he continued until May, 1923. He then went to Reading, Pa., where he was associated with the W. S. Barstow Management Association, until September, 1924, as mechanical engineer in charge of design and construction of a power plant at Middletown, Pa., for the Metropolitan Edison Company. From that time until his death, which occurred at New York on January 29, 1937, Mr. Coster was engineer of mechanical design for the Interborough Rapid Transit Company.

His widow, Mary (Seward) Coster, whom he married in 1903, a daughter, Elizabeth, of Holyoke, Mass., and a son, Herbert S. Coster, of Orange, N.J., survive him.

Mr. Coster became a naturalized citizen of the United States in 1906 and a member of the A.S.M.E. in 1910.

DUDLEY PEAK CRAIG (1890–1937)

Dudley Peak Craig, head of the Mechanical Engineering Department of the Colorado State College, Fort Collins, Colo., died on March 26, 1937, of pneumonia.

Mr. Craig was born in Ghent, Ky., on November 8, 1890, the son of Ulysses Peak and Mollie (Davis) Craig. His early education was obtained in the Manual Training High School of Indianapolis, Ind., and his engineering course was taken in Purdue University, where he was graduated with a B.S. degree in mechanical engineering in 1912, and in 1924 was granted an M.E. degree.

On graduating in 1912, Mr. Craig went to work with the Western Electric Company, Chicago, Ill., where he remained five years. His work was devoted particularly to manufacturing methods and time study, and the development of lead-covered cable. From 1917 to 1918, Mr. Craig was employed by Landers, Frary & Clark, New Britain, Conn., on time studies and factory costs. In 1918, he was in the U.S. Army in a field artillery officers training camp, but soon afterwards took a position with the Firestone Tire & Rubber Co., Akron, Ohio, where he stayed until 1921. He was attached to the Industrial Engineering Department in charge of the factory suggestion system.

In 1921, Mr. Craig returned to Purdue University as instructor and graduate student, obtaining his M.E. degree in 1924. He was appointed assistant professor in 1925, and associate professor in 1931. He remained in this position until September, 1936, when he went to Fort Collins, to take over the chair of mechanical engineering and head of the department at Colorado State College, following the retirement of Prof. L. D. Crain.

Professor Craig joined the A.S.M.E. as a member in 1925. He was honorary chairman of the A.S.M.E. Student Branch at Colorado State College at the time of his death. He was also a member of the Society for the Promotion of Engineering Education and corresponding secretary of its Rocky Mountain Section, belonged to the Tau Beta Pi and Pi Tau Sigma fraternities, and held the rank of major in the U.S.A. Field Artillery Reserves. In collaboration with Hubert J. Anderson, he was author of a book, "Steam Power and Internal Combustion Engines," which was brought out by the McGraw-Hill Book Company in 1931 (revised edition in 1937). Like many other young engineering students and instructors, Professor Craig engaged in occasional outside work; thus he worked as machinist apprentice for the Big Four Railroad, Beech Grove, Ind., during the summers from 1908 to 1911, and also put in another summer (1924) with the Cleveland Electric Illuminating Company, on acceptance tests of powdered coal boilers, and contributed papers to the *Purdue Engineering Review* and to *Power*.

In 1914, Professor Craig married Bessie Sheffer, of Chicago. He is survived by her and their four children, Gordon Davis, Mary Ruth, Elizabeth Ann, and Donald John, as well as by his mother and three brothers, all engineers.

CALVIN HENRY CROUCH (1870–1937)

Calvin Henry Crouch, a resident of Cliffside Park, N.J., died suddenly in Oswego, N.Y., on July 13, 1937, shortly after attending a reunion of his Class of 1892 at Cornell University.

Mr. Crouch was born on April 25, 1870, near Oswego, N.Y., the son of Henry Theodore and Ruth Lydia (Kenyon) Crouch. He prepared for college in the Oswego public schools and then attended Cornell University, where he was graduated with an M.E. degree.

Immediately after his graduation, Mr. Crouch spent a year as a student apprentice with the Ames Iron Works, Oswego. He then worked for a year with the Rome, Watertown & Ogdensburg R.R., Oswego, as a machinist, and followed this position by working for three years, from 1894 to 1897, as erecting engineer and in experimental and test work with the Deane Steam Pump Company of Holyoke, Mass. He next spent three years as instructor in machine shop practice at the Williamson Free School of Mechanical Trades, Delaware County, Pa. This was followed by one year erecting locomotives in Europe as traveling engineer for the Baldwin Locomotive Works, of Philadelphia, Pa.

In 1901, Mr. Crouch went to the University of North Dakota, Grand Forks, N.D., as dean of the College of Mechanical and Electrical Engineering and professor of mechanical engineering. He held this appointment until 1916, when all the engineering interests in the university were combined into the College of Technology. Under the reorganization, Mr. Crouch became professor of mechanical engineering and director of shops.

In 1919 Professor Crouch took the position of acting dean of the College of Technology and professor of mechanical engineering at the University of New Hampshire, Durham, N.H. He became dean the following year and remained at the college until 1925. From then until 1932, he was employed by E. L. Phillips & Co., New York, N.Y., as mechanical engineer.

In 1898, Mr. Crouch married Della L. Newman of Oswego, N.Y., who survives him.

He joined the A.S.M.E. as an associate in 1898, and became a member in 1908. He was also a member of the Society for the Promotion of Engineering Education. Mr. Crouch was a Knight Templar in the Masonic order, a Baptist in religion, and a Republican in politics. His paper, "Experiments With North Dakota Lignite in a Steam Power Plant and a Gas Producer," was published in the A.S.M.E. Transactions (vol. 34, 1912, page 795), and the University of North Dakota published a Bulletin by him, "Vocational Training." He also wrote several papers that were published in the Proceedings of the S.P.E.E.

ARCHER DAVIDSON (1881–1938)

Archer Davidson, sales engineer at Boston, Mass., for the Westinghouse Electric & Manufacturing Co., died on July 7, 1938. Mr. Davidson was born on February 18, 1881, at Farmville, Va., the son of William and Julia Flippen (Wiltsie) Davidson. His education consisted of six years at public schools, two years at Farmville High School, and three years at the Virginia Polytechnic Institute, Blacksburg, Va., where he received a B.S. degree in June, 1902.

During a portion of the time Mr. Davidson spent at the Virginia Polytechnic Institute, he worked at steam fitting in Lynchburg, Va., and also on the power plant and steam-heating system for the Virginia State Normal School for Women. Upon his graduation from college, he went to work as an apprentice machinist with the Westinghouse Machine Company, Pittsburgh, Pa., and was soon promoted to assistant foreman in the steam turbine Erecting and Testing Department.

In 1903, he was made an assistant in the Turbine Test Department and was employed as erecting engineer, under the direction of Westinghouse, Church, Kerr & Co., in connection with installations at two plants in Maine. In 1904 he returned to the Westinghouse Machine Company as erecting engineer, and during the following year he was connected with the installation of some twenty turbine units for plants furnishing power for cotton mills, electric railway and lighting service, and general industrial purposes.

Mr. Davidson was appointed district engineer for the Atlanta District of the company in 1905, and remained there until 1915, when he was transferred to the Boston Office as sales engineer, in which work he continued until his death. He was highly regarded in engineering circles for his ability and experience in the design, operation, and application of steam equipment, and he was responsible for many of the large turbine installations throughout New England.

During his long service with the Westinghouse organization, Mr. Davidson took out a number of patents. Probably the most outstanding was one covering the combination impulse and reaction turbine exploited by the Westinghouse Machine Company, which materially shortened the length of the turbine as compared with one of equal power having all reaction blading. This patent was sufficiently broad in scope to cover any combination type turbine.

A second patent of importance covered a power plant arrangement wherein with an existing non-extraction type turbine, an extraction type is installed with feedwater heaters supplied from the extraction type unit, serving to progressively increase the temperature of condensate passing from the condensers of both turbines to separate boilers, the boiler supplying steam to the extraction turbine operating at higher pressure and temperature with the object of improving the overall performance.

Mr. Davidson married Florence Meadows in 1922 and is survived by her and by two sisters. He joined the A.S.M.E. in 1907 as an associate.

HENRY S. DEMAREST (1867–1937)

Henry S. Demarest died on July 11, 1937, at his home in Hempstead, L.I., N.Y., after a long illness. Mr. Demarest was president and treasurer of Greene, Tweed & Co., New York, N.Y., manufacturers of mill supplies. He was the son of Albert Alonso and Constance Marie (Eakin) Demarest and was born on February 1, 1867, in Brooklyn, N.Y., in the public schools of which city he obtained his education.

Mr. Demarest began his business career with the Worthington Pump & Machinery Co., then known as Henry R. Worthington. While with that firm his attention was drawn to a little-known brand of asbestos packing. The qualities of this packing so impressed him that he gave up the lucrative position he held and persuaded Greene, Tweed & Co., the manufacturers of the packing, to permit him to attempt to place their product on the market. His untiring efforts, judgment, and faith in the product were eventually rewarded, the packing becoming well and favorably known throughout the world. Later Mr. Demarest acquired the controlling interest in the company.

Besides his own business, Mr. Demarest was a director of the Union Ferry Company of New York and Brooklyn. He was a vice-president of the American-Polish Chamber of Commerce and was decorated by the Polish government with the medal of the Order of Polonia Restituta. During the first World War, he was a member of the Executive Committee of the Hardware Metals and Allied Trades Committee.

Mr. Demarest became an associate of the A.S.M.E. in 1914. He was also a member of the Union League Club, the Merchants Club, the Export Managers Club, the British Chamber of Commerce, the Huguenot Society, and the Holland Society of New York.

Mr. Demarest's chief hobby was his business; but he was also keenly interested in his library and garden.

He is survived by his widow, Mrs. Frieda J. (Nicholas) Demarest, whom he married in 1931, in London, England.

HERMAN DIEDERICHS (1874–1937)

Herman Diederichs was elected a junior member of the A.S.M.E. in 1904 and promoted to full membership in 1913. In 1930 the Melville Medal of the Society was awarded jointly to him and to William D. Pomeroy for their paper entitled "The Occurrence and Elimination of Surge or Oscillating Pressure in Discharge Lines From Reciprocating Pumps."

He was appointed a member of the Committee on Awards of the Society in 1933 to fill an unexpired term and served as chairman of the committee during 1936. He was also a member of the Nominating Committee for 1936. He served as a member of the Power Test Codes Committee on Reciprocating Steam Engines from 1918 until his death, and as a member of the Special Research Committee on Bearing Metals from its appointment in 1916 until its discharge in 1927. He was a representative of the Society on the Division of Engineering and Industrial Research of the National Research Council from 1930 to 1933.

Dean Diederichs had been on the faculty of the College of Engineering of Cornell University since his graduation there in 1897. The following memorial is adapted from an obituary by Dexter S. Kimball (whom he succeeded as dean of the College of Engineering) which was published in *The Cornell Engineer*, October, 1937. The same issue contained tributes by others who had been associated with him, including Livingston Farrand, S. C. Hollister, P. M. Lincoln, W. N. Barnard, and Albert W. Smith.

Dean Herman Diederichs passed away on August 31, 1937, at Clifton Springs (N.Y.) Sanitarium of an obscure anemic disease and after several months of illness. His death removes another of the outstanding figures that have not only made famous the College of Engineering of Cornell University, but who, by reason of their personal characteristics, gave luster to the entire institution.

Dean Diederichs was born in Muenchen-Gladbach, Germany, August 12, 1874, and received his elementary education there. He was the son of Johann Peter and Anna Marie (Kamps) Diederichs, and was the oldest of a family of six, all of the remainder of whom survive him. These are Mrs. Katherine Shafer, of Brooklyn, N.Y.; Mrs. Louise Weber, of Waterbury, Conn.; P. Paul, of Dolgeville, N.Y.; Hugo N., of Owens, W.Va.; and William J., of Upper Darby, Pa.

In 1888 his parents migrated to this country and settled in Dolgeville, N.Y. The family was one of modest circumstances, yet means were found to send him and others of the family to high school at Dolgeville, where he won a state scholarship. He walked to Herkimer, more than twenty miles distant, to take the competitive examinations. With this and a promise of financial assistance from friends (which did not materialize), he entered Cornell University in 1893. Here, largely through his own exertions, he not only completed his course in engineering in the prescribed four years, with such a good record as to be elected to the honorary society of Sigma Xi, but he also found time to engage in student activities and was

prominent as a shot-putter. He graduated with the degree of M.E. in 1897, which, for a person who had to learn English at fourteen years of age, must be considered as an accomplishment.

He won the first Sibley prize in his senior year and the Sibley Fellowship for graduate study. After a year on this fellowship he was appointed an instructor in experimental engineering under Professor Rolla C. Carpenter. In 1902 he was promoted to an assistant professorship, to a professorship in 1907, and succeeded Professor Carpenter as head of the Department of Experimental Engineering in 1920. In 1928 he was appointed the first incumbent of the John Edson Sweet Professorship, founded in honor of the distinguished engineer who at one time was a professor at Cornell. In 1921 he became director of the Sibley School of Mechanical Engineering and in 1936 he was appointed to the deanship of the College of Engineering—a well-deserved honor, which he was fated to enjoy only for a little over one year.

His entire manhood was, therefore, devoted to the service of his alma mater, not only in his chosen field, but in many of the broader aspects of university life. No man of the faculty was called upon more frequently to serve on important committees, and the confidence of his colleagues in his sound judgment and honesty is attested by his election by the university faculty in 1929 to serve as one of the faculty representatives on the Board of Trustees, which office he filled for three years. Space does not permit even an enumeration of the many services of this sort that he rendered to the university community. His service to the College of Engineering was even greater. For many years no important question whether of academic or administrative character has been decided without seeking his advice and judgment. The curriculum of mechanical engineering, in particular, has been shaped under his guiding hand. He was indeed a wise adviser.

He was no less active and interested in the problem of student life. Interested naturally in athletics, he was for many years a member of the Athletic Association and for some years served as president of that body. Here, again, his sterling character impressed itself upon the difficult problems of athletics, and that this was amply appreciated by the student body is shown by the following dedication of *The Cornellian* of 1935:

"To Herman Diederichs, who for forty-two years has served his alma mater as student, teacher, and administrator, and, who, through his intense interest and untiring efforts, has succeeded in inaugurating a new era in Cornell athletics. For his active participation in campus affairs, he will long be remembered, and as a stern teacher and a sympathetic, honest friend, the Class of 1935 will revere him—Cornell's Man of the Year."

Surely student praise can attain no higher level of appreciation.

He was vice-president of the second district of the National Collegiate Athletic Association and chairman of the Board of Athletic Control of Cornell University.

Dean Diederichs was essentially a man of scholarly mind and his outlook on life was naturally colored by this fine quality. He was an authority in the field of experimental engineering. In 1905 he and Professor Carpenter collaborated in writing a treatise entitled "Internal Combustion Engines" and in 1911 they produced "Experimental Engineering," which is a standard work in that field. In 1930 he and Professor W. C. Andrae collaborated in a monumental treatise entitled "Experimental Mechanical Engineering" (Volume I, Engineering Instruments) and Volume II, on testing of power plant apparatus, was in preparation. He also translated Güldner's "Internal Combustion Engines" from the German. He contributed a number of articles to the *Sibley Journal* and other publications, beginning as early as 1900. Among these were "Analysis of Coals," "Comparative Tests of Plain and Para-Pneumatic Pulleys," and several reports on gas-engine tests. He was the co-author of three bulletins of the Engineering Experiment Station at Cornell, dealing with "The Purification of Salt Made From Central New York Brines," "The Heat Transfer From Steam to Heavy Fuel Oil," and "Flame Propagation in Closed Cylinders." He also made many tests and investigations as a consultant, among which may be mentioned a power test on the steamer *Morro Castle*, of the Ward Line, a report on a plant for the production of oxygen, for the American Oxygen Company, and, particularly, a voluminous report on the power plant of the Hall of Records in New York, N.Y. This test consumed a year and the report constitutes a book of 673 pages.

Dean Diederichs was also a member of the following honorary and scientific societies: Quill and Dagger, senior honorary society; Phi Sigma Kappa fraternity; Sigma Xi; Tau Beta Pi; Phi Kappa Phi; Society of Automotive Engineers; American Society for Metals; Verein deutscher Ingenieur; and Society for the Promotion of Engineering Education.

His teaching naturally reflected his scholarly habits and Germanic thoroughness. He had little sympathy with lazy or indifferent students, but he would go to any length to make a point clear and no student went to him for help and came away empty-handed. Perhaps his best teaching work was his lectures on materials of engineering given to many generations of electrical and mechanical engineers and which, in the opinion of the writer, were classics. He was an excellent lecturer and could interest the student in this highly technical subject. Of lasting value also is his work in helping to develop the present course in experimental engineering than which there is none better, if as good, in this country. It should be remembered that the engineering experimental laboratory was conceived by Dr. Robert H. Thurston at Stevens Institute and brought by him to Cornell in 1885. The background of the present course was developed under his guidance by Professor Rolla C. Carpenter and has been widely copied elsewhere. Professor Diederichs, therefore, drank from the original source and carried with him to his death the inspiration of these two great pioneers. It has been his labor to modify and adapt the course to an ever changing industrial world and this he has done in a masterly manner, keeping the course in advance of the times, though almost always handicapped for lack of money and equipment. It was this same inspiration that enabled him to keep the spirit of research alive in mechanical engineering, for, in spite of many handicaps, too many to enumerate, the long list of scientific publications issued under his guidance has continued to grow. His influence and knowledge in this important side of the work of the college will be one of its heaviest losses, and one that will be impossible to compensate for. Men of his thorough scholarly and scientific background and long experience in experimental work are rare indeed, and difficult to replace. One of the reasons for his wide and deep knowledge lay in his omnivorous reading, not only of scientific and engineering literature, but also of a broad general character, and this wide reading habit embraced German literature as well as American and English. He was a very well-informed man.

I have always held him in high regard as an administrator. He was my close friend for nearly forty years, and my most valued adviser during my deanship. Not that we have always agreed on all matters, but because of his openmindedness it was always possible to come to a conclusion that seemed best and which was mutually satisfactory. He never allowed his personal feelings or opinions to affect in any way the welfare of any member of the faculty, and his interest in the life of the college was deep and fair-minded. He had certain definite policies for the future of the college, which I had hoped he would have an opportunity to develop, but fate ordained otherwise. That these good qualities were fully appreciated by his colleagues, was attested by the almost unanimous vote by which his nomination was approved.

His relations to his students were quite unique. Despite the fact that he was a bachelor, he had a real fondness for young people and sympathy with their problems. He was far from being a demonstrative person, and his rather severe countenance and somewhat brusque manner were often forbidding to the new student. It usually took some experience with him to discover that this rough exterior hid a warm and understanding heart. Dr. C. F. Hirshfeld, in an appraisal of him on the occasion of his appointment to the deanship, has very aptly expressed this quality thus—"In some respects the poorer scholars and breakers of rules and regulations among the older classes were more fortunate than those who traveled the straight and narrow path of scholarship and good conduct. Many of the weak, the lame, and mischievous who appeared before Professor Diederichs and his associates, by special though not sought after invitation, discovered that back of the severe manner of the strict disciplinarian there dwelt a kindly, understanding, and human living soul." He had a fine sense of humor through which he could always view student manners, and he was fond of relating humorous situations that arose in his contacts with underclassmen. Only a short time ago he related to me with glee, two absolutely new and equally spurious reasons advanced by freshmen, why it was imperative for them to get away several days before the beginning of the spring recess. He said that because the reasons were at least new and ingenious, though of doubtful validity, he granted the requests and laughed heartily.

No student ever went to him for advice or help on any matter without receiving assistance, and as freshmen grew into seniors, they acquired respect, admiration, and often real affection for this rugged and unique personality. To hundreds of returning alumni, the campus will not be quite the same, because "Died" will not be there.

One of Dean Diederichs' most outstanding virtues was his essential honesty, not only in matters pertaining to his professional work and his teaching, but in all his personal contacts with people. I have never known a man on whose word I could more thoroughly rely, or one of greater integrity, in all the many transactions that transpired between us. He was modest to an extreme degree, which accounted, no doubt, for some of his apparent great reserve. He was a sociable man, fond of company, and a first-class companion. His wide range of reading enabled him to converse intelligently on almost any topic. Frailties he no doubt had, as have all of us, but they were over-

shadowed by his rugged, upstanding personality, and by the many helpful services he rendered to all around him. Like Joseph of Arimathæa, "he was a good man, and a just," and Cornell University and this entire community are the better because he lived and worked among us.

AMELIA EARHART (1898–1937)

Amelia Earhart was born in Atchison, Kan., on July 24, 1898, the daughter of Edwin S. and Amy Otis Earhart. She was educated in the Hyde Park High School of Chicago, at Columbia University, and at various other colleges. From 1926 to 1928, she was in charge of the girls' work at Denison House in Boston, and also taught an extension course for the Commonwealth of Massachusetts. On June 17, 1928, she was the first woman to cross the Atlantic Ocean in an airplane, going from Trespassey Bay, Newfoundland, to Burryport, Wales. From 1928 to 1930, she was aviation editor of the *Cosmopolitan Magazine*, and began her career as a pioneer. She has been described as the first woman to fly the Atlantic alone, the first person to fly the Atlantic alone twice, the first woman to fly an autogiro, the first person to cross the United States in an autogiro, the first woman to receive the Distinguished Flying Cross, the first woman to fly nonstop across the United States, and the first woman to fly from Hawaii to the United States.

In 1931, she married George Palmer Putnam, who cooperated in every way to make her flying possible and to encourage her in her pioneer work. The best account of her achievements and her interests is contained in her two books, "20 Hours, 40 Minutes," published in 1928, and "The Fun of It," published in 1931. They show her two chief interests to have been flying and furthering the progress of aviation, and increasing opportunities for women to select and go forward into careers and at the same time, enjoy home and family life.

Purdue University is proud that Amelia Earhart became a member of its faculty and made outstanding contributions, both in the field of aeronautics and in that of careers for women. Her "Flying Laboratory" in which she made her last flight was financed by men affiliated with Purdue, and the tragic ending in July, 1937, of her exploratory trip around the world, which shocked and saddened the entire world, took from Purdue not only a valued and inspiring leader, but a beloved friend. Her portrait hangs in one of the residence halls for women and each of the three residence halls has a memorial library maintained by the students in affectionate recognition of her contributions. President Edward C. Elliott has characterized her perfectly in a speech made on the Purdue campus at a Conference on Women's Work and Opportunities, October 31, 1937, when he said, "Her primary interest in life was not in this career of adventure upon which she had embarked, but rather in an effort to find and make some addition to the solution of the problem of careers for women."

Miss Earhart had many honors and medals. She was a member of many technical groups, including the A.S.M.E., which she joined as an associate in 1931, and of many nontechnical groups and clubs. Her contributions can be measured by her achievements, but also include stimulating and encouraging youth everywhere to adventure and to achievement.—[Memorial prepared by LILLIAN M. GILBRETH, Montclair, N.J., Mem. A.S.M.E.]

RALPH EARLE (1874–1939)

Ralph Earle, Rear-Admiral, U.S. Navy, Retired, president of Worcester Polytechnic Institute, died at Worcester, Mass., on February 13, 1939. He had been president of the Institute since 1925 and was made a member of the A.S.M.E. in 1926.

President Earle was descended from the early settlers of Leicester, Mass. He was born in Worcester, May 3, 1874, son of Stephen Carpenter and Mary Eaton (Brown) Earle, and after his early education in the public schools of Worcester, was admitted to the Worcester Polytechnic Institute in January, 1892. A few months later, he took the competitive examination for entrance to the United States Naval Academy at Annapolis, won the appointment, and was graduated there in 1896.

He was promoted through the various commissioned grades of the Navy, serving in the war with Spain, the World War, and in the Philippine and Mexican Campaigns. He soon became conspicuous in matters pertaining to naval ordnance, and in 1916, shortly after attaining the rank of captain, he was made the Chief of the Bureau of Ordnance, with the rank of Rear-Admiral during the exacting World War period. He was responsible for the conception of two of the outstanding activities in which the American Navy was engaged during the World War. The first had much to do with the defeat of the enemy's submarine warfare and consisted of the design and construction of a mine barrage across the North Sea. This barrage consisted of a submerged mine field 230 miles in length and 25 miles wide and was the culminating step in combatting the submarine.

The second accomplishment was that of the design and the construction of the 14-inch railway batteries which saw active service in France. These naval guns were the largest at the front and resulted in cutting the enemy's main line of communication and unquestionably paved the way for the Armistice.

In 1925, he retired from the Navy to accept the call to become the president of the Worcester Polytechnic Institute in his native city. His record there was one of marked progress for the school, both professionally and materially, and, at the time of his sudden death in 1939, his comprehensive plan to keep that well-established school abreast the field of engineering was well under way and is now being pushed to completion. As sixth president of the Institute, his administration will be long remembered for the success which he achieved in training youth for leadership in the world of science and engineering.

Admiral Earle was a Bachelor of Science, United States Naval Academy, and received the following honorary degrees: D.Sc., Worcester Polytechnic Institute, 1925; D.Eng., Rensselaer Polytechnic Institute, 1926; LL.D., Amherst College, 1929; and LL.D., Clark University, 1930. During his naval career, he was honored with many decorations both by his own and foreign countries. He was a member of the Society of Naval Architects and Marine Engineers and of the Society for the Promotion of Engineering Education, as well as of a number of other societies and clubs, and was the author of several books.

President Earle is survived by his widow, Janet Turner (Schenck) Earle, whom he married in 1898 and who is the daughter of a naval officer; a son, Ralph, Jr., who is a naval officer; and a daughter, Mary Janet Hines, who is the wife of a naval officer.

President Earle's whole career was stamped with the loyalty engendered in his early naval life and he had to an unusual degree the gift of winning the loyalty of his subordinates. Added to this gift were his human qualities which made him beloved by all with whom he came in contact.—[Memorial prepared by ADMIRAL WAT TYLER CLUVERIUS, President, Worcester Polytechnic Institute.]

CHARLES ISAAC EARLL (1863–1938)

Charles Isaac Earll, of York, Pa., died in New York, N.Y., on June 14, 1938, while on a business trip. He was severely injured in an automobile accident near Norwalk, Ohio, on October 28, 1937; and although he apparently recovered from the effects of the accident, he was never well for long afterward, and his death, eight months later, was probably an indirect result of the injuries sustained at that time.

Mr. Earll was born at Van Buren, N.Y., on April 11, 1863, the son of Myron H. and Asenath (Styles) Earll. He obtained his preparatory education at the State Normal School, Whitewater, Wis., and was graduated with a B.S. degree in mechanical engineering from the University of Wisconsin in 1885. He later took one and one-half years' work in the New York Law School.

Immediately on his graduation from the University of Wisconsin, Mr. Earll went to work for the Filer & Stowell Co., Milwaukee, Wis., as machinist and draftsman in the building of steam engines and sawmill machinery. From 1886 through 1890, he worked as draftsman and designer on the Paige typesetter, an enterprise conducted by James W. Paige, Hartford, Conn., and financed by Samuel L. Clemens (Mark Twain). In January, 1891, Mr. Earll went to New York and was employed as assistant engineer on the several cable-operated street railways then in use on Broadway, Columbus, Seventh, Ninth, and Lexington Avenues, and Twenty-Third Street.

From 1894 to 1898, Mr. Earll was superintendent of shops for the De Laval Separator Company, Poughkeepsie, N.Y., and from 1898 to 1915, he practiced in New York as patent solicitor and consulting engineer. In 1915, he established his own business in York, Pa., manufacturing trolley catchers and trolley retrievers, and continued in that work until his death.

During his long professional career, Mr. Earll took out a number of patents relating to cable railways and grips for these railways; also on a geared hoist and on a reel for clotheslines, and several on springs, working mechanisms, and other details for trolley catchers and retrievers.

Mr. Earll became a member of the A.S.M.E. in 1892. He served on the Publications Committee of the Society from 1911 to 1917, being chairman in 1914 and 1915; and on the Executive Committee of the Susquehanna Section in 1928–1930. He was also a member of the Engineering Society of York, and of the Manufacturers' Association, the Chamber of Commerce, the Lafayette Club, the Country Club, and the Rotary Club, all of York, and of the Engineers' Club, of New York.

In 1905, Mr. Earll married Mary H. Flynn, of New York, who survives him.

SAMUEL SUMNER EDMANDS (1877–1938)

Samuel Sumner Edmands was born in Kalamazoo, Mich., on April 30, 1877, his father being John Edmands, and his mother Maria (Goodwin) Edmands. His formal technical education was received at Worcester Polytechnic Institute, Worcester, Mass., where he was graduated in 1899. During the following year he was employed by the American Telephone & Telegraph Co., Providence, R.I. In 1900 he returned to the Middle West, serving as instructor in electrical engineering at Ohio State University for one year. In 1901 he began his service at Pratt Institute, Brooklyn, N.Y., where he was destined to continue for thirty-seven years, and to leave his imprint on the development of technical education of the technical institute type in this country.

He served Pratt the first year as instructor, and became head of the electrical department the following year. In 1910 Arthur L. Williston retired from his position as director of the School of Science and Technology at Pratt to become principal of Wentworth Institute, at Boston, and the young head of the electrical department was elevated to fill his position.

The period which followed 1910 was an important one for technical institutes. They were to be called upon, with other educational institutions, to give preliminary trade training to United States soldiers in 1918, and later, from 1919 to 1925, to train many demobilized soldiers who had been wounded in service, or whose physical weaknesses had been aggravated by service. For this work the technical institute type of institution proved very useful, for it was accustomed to devise courses to meet specific needs, and was free of the inertia of large educational systems. Those interested in such courses found much to learn at Pratt Institute, because of the prominent position of this institute in its field. During all this period Director Edmands was quietly effective. During more recent years he expanded the Institute's two-year course to three years, with an optional fourth year for a degree.

Director Edmands joined the A.S.M.E. in 1923 and was a member of the Committee on Education and Training for the Industries from 1924 to 1933. He declined the chairmanship of this committee because of the pressure of other duties. His service on the committee was wholehearted. He helped select many of the papers that were presented at the meetings, and his acquaintance with educators and industrial leaders in the East brought the committee into contact with effective speakers in the field of education for industry. He was also a member of the Brooklyn Engineers' Club, and of the Society for the Promotion of Engineering Education.

In 1930 Director Edmands received the honorary degree of Doctor of Engineering from Worcester Polytechnic Institute. Efforts to attract him to positions of greater apparent prominence in education failed to move him from Pratt Institute. He was primarily interested in the development of the technical institute type of course with which Pratt Institute had long been identified, and in which his own influence had been great.

Dr. Edmands' death on May 24, 1938, was the result of injuries suffered in the crash of an automobile in which he was a passenger. He was at the height of his powers and would have made a considerable additional contribution to the field in which he had already done much, had he been spared. He was married in 1905 to Althea Florence Miller, of Brooklyn, N.Y., and is survived by his widow and a daughter, Miss Patricia Edmands.—[Memorial prepared by JOHN T. FAIG, Cincinnati, Ohio, Mem. A.S.M.E.]

LOUIS G. ENGEL (1859–1938)

Louis G. Engel, who retired from active professional work about 1905, died on April 19, 1938, at his summer home, New Canaan, Conn. Mr. Engel was born on November 29, 1859, in Brooklyn, N.Y. He was the son of Frederick Eberhard and Caroline Leonora (Gunzenhauser) Engel. He attended Brooklyn public schools, and then entered the School of Mines of Columbia University, where he was graduated with the Class of 1880 with the degree of Mining Engineer (E.M.). He then served a partial apprenticeship in shop work, and became familiar with ordinary machine tools.

This was followed by three years' service as mining engineer for the Tilly Foster Iron Mines, Tilly Foster, N.Y., where he had direct charge of all underground work. He was then employed for about three years as draftsman by the Brooklyn Sugar Refining Company and for over a year further as superintendent of construction, with full responsibility for all new work. About 1890, Mr. Engel associated himself with the New York Sugar Refining Company, under the presidency of Claus Doscher. This company later became the National Sugar Refining Company, and Mr. Engel remained with it until his retirement in 1905.

Mr. Engel married Miss Gesine Doscher, who survives him. He became a member of the A.S.M.E. in 1887.

ROBERT HEYWOOD FERNALD (1871–1937)

Robert Heywood Fernald, director of the Mechanical Engineering Department and dean of the Towne Scientific School of the University of Pennsylvania, died on April 24, 1937, in the University of Pennsylvania Hospital, Philadelphia, Pa., of a heart ailment, following a long illness.

Dean Fernald was the son of Dr. Merritt Caldwell Fernald, a former president of the Maine State College of Agriculture and the Mechanic Arts (now the University of Maine), and Mary Lovejoy (Heywood) Fernald. He was born in Orono, Maine, on December 19, 1871, prepared for college in the Orono High School, and was graduated from Maine State College with a B.S. degree in mechanical engineering in 1892. He did graduate work at the Massachusetts Institute of Technology, 1892–1893, and in 1898 was granted an M.E. degree by the Case School of Applied Science. He was a Fellow in Columbia University in 1900–1902, obtaining the A.M. degree there in 1901, and the Ph.D. in 1902.

It was not at all Dr. Fernald's ambition as a young man to take up educational work—he had architecture in mind; but following his graduate work at M.I.T., he ran into the depression of 1893, and being offered an instructorship in mathematics and mechanical engineering at the Case School of Applied Science, he accepted it, and decided to teach until economic conditions improved. He liked his work so well that he never subsequently dropped it, although he found time to engage in a wide variety of consulting and professional work.

In 1900, Dr. Fernald left the Case School, where he had been assistant professor of mechanical engineering since 1896, to take a fellowship at Columbia University. Upon the completion of his work there in 1902 he became professor of mechanical engineering at Washington University, St. Louis, Mo., and remained there until 1907, when he returned to the Case School to head its Mechanical Engineering Department. In 1912, he was called to the University of Pennsylvania as Whitney professor of dynamical engineering and director of the Mechanical Engineering Department. In February of 1930, Dr. Fernald was made dean of the Towne Scientific School, which appointment was terminated only by his death.

In addition to his several earned degrees, the University of Pennsylvania in 1924 conferred upon Dr. Fernald the honorary degree of Doctor of Science. He was also a member of the honorary fraternities of Sigma Xi, Phi Kappa Phi, Tau Beta Pi, and Phi Beta Kappa. He became an associate of the A.S.M.E. in 1900, member in 1903, and Fellow in 1936. He was an active member of the Society for the Promotion of Engineering Education. He was a member of the Joint Committee of the National Industrial Conference Board and Society for the Promotion of Engineering Education on relations between technical education and the industries, 1922–1928; and served as official representative of the Towne Scientific School in the Society for the Promotion of Engineering Education. He belonged to The Franklin Institute, and served as president of the Cleveland Engineering Society in 1912. He was a secretary of the Engineers' Club of Philadelphia in 1916, its president in 1922–1924, and a member of its Board of Directors, 1924–1927. His club memberships included the Engineers, University, Manufacturers, and Lenape clubs, of Philadelphia.

Dr. Fernald directed and conducted extensive investigations in the United States and Europe for the U.S. Geological Survey and Bureau of Mines and prepared exhaustive reports for these bureaus. He was engineer-in-charge of the Technologic Branch, U.S. Geological Survey, from September 1, 1904, to July 1, 1910, and consulting engineer, Fuel Division, Bureau of Mines, July 1, 1910–1920. As consulting engineer for the Public Service Commission of Pennsylvania, 1913–1915, he formulated rules and regulations for gas, heating, and water utilities of Pennsylvania. He was a member of the Conservation State Board, Pennsylvania, U.S. Fuel Administration, 1918–1919, engineer-member, Giant Power Survey Board of Pennsylvania, 1923–1926; member, Executive Committee, Third World Power Conference, 1935–1936; member, Science Advisory Committee, Mechanical Engineering Division, Chicago Century of Progress Exposition, held in 1933; member, Board of Directors, Philadelphia Sesquicentennial Exposition, held in 1926; member, Executive Committee, Traffic Commission, City of Philadelphia, 1930–1933; member, Greater Pennsylvania Council, 1931; chairman, Committee on Development of Pymatuning Area, Mercer County, Pa.; honorary vice-chairman, Engineers' National Hoover Committee, Pennsylvania Section, 1932; engineer-member, Advisory Committee, Philadelphia Agency of the Reconstruction Finance Corporation, 1932–1933; and chairman, Executive Committee, Technical Advisory Council affiliated with Philadelphia Chamber of Commerce, 1936–1937. He also carried on a general consulting practice in mechanical engineering, especially in fuels and power,

and made commercial investigations for numerous firms and individuals.

An easy and prolific writer, Dean Fernald contributed many papers, not only to purely technical journals, but to many non-technical periodicals. He was also the co-author, with G. A. Orrok, of a 600-page university textbook, "Engineering of Power Plants," which passed through three editions, 1916, 1921, and 1927.

As a member of the A.S.M.E., Dr. Fernald served with competence and loyalty. He was a manager of the Society, 1916–1919, and vice-president, 1920–1921. He was one of the Society's delegates to the American Engineering Council in 1921. His committee service began in 1911, when he became chairman of the Gas Power Section. He was chairman of the Executive Committee of the Philadelphia Section in 1915–1916, and a member of the Meetings and Program Committee, 1913–1917, serving as chairman the last year. He was a member of the Power Test Codes Committee from 1918 until his death, and was appointed its acting chairman in 1933 and permanent chairman in 1936. He was temporary chairman of Power Test Codes Committee No. 16 on Gas Producers during its first year, 1918–1919, and continued as a member of the committee until his death.

In June, 1905, Dr. Fernald married Catherine Mason Coupland, of Boone, Iowa. They had three children: Merritt Caldwell, Frances Mason, and Mason. His widow and two sons survive him. He also had three brothers, Merritt Lyndon Fernald, Fisher Professor of Natural History, Harvard University, George Bancroft Fernald, Master of English at St. Marks School, Southborough, Mass., and Reginald Lovejoy Fernald, proprietor of the Pratt Teachers Agency, New York, N.Y.; and a sister, Harriet Converse (Fernald) Pierce.

WESLEY MONTEITH GRAFF (1890–1937)

Wesley Monteith Graff, director of the Safety Engineering Division of the National Bureau of Casualty and Surety Underwriters, New York, N.Y., died on June 5, 1937. Mr. Graff was born on May 11, 1890, in Brooklyn, N.Y., the son of Charles Edward and Margaret (Barclay) Graff. He was educated in the Polytechnic Preparatory School, Brooklyn, and in the Sheffield Scientific School of Yale University, where he obtained a Ph.B. degree in 1911 and M.E. degree in 1913.

Mr. Graff's first practical experience was secured during his college vacations: In 1910, with the Pennsylvania Tunnel & Terminal R.R. Co., as draftsman in connection with tunnels and terminals in New York, and as assistant engineer on acceptance tests of electric locomotives; in 1911, with the Hartford Electric Light Company, in charge of an investigation and cost-comparisons of steam and water power for central-station use; in 1912 and 1913, with the Edison Electrical Illuminating Company of Brooklyn as assistant power engineer on sales of industrial electric power, and laying out and supervising the installation of industrial power, heating, and lighting equipment.

After his graduation, from September, 1913, to April, 1918, Mr. Graff was employed by the Graves Engineering Co., Inc., New York, consulting engineers, first as chief mechanical engineer, and, from October, 1917, as vice-president. His work chiefly concerned the design, construction, and operation of electric public utilities; design, specifications, investigations, and reports pertaining to industrial power, heat, and illumination; studies of special mechanical manufacturing processes; and the design of special machinery.

Mr. Graff served from April, 1928, to December of the same year with the Engineering Division of the Ordnance Department, Washington, D.C., as director of the preparation of specifications for the Motor Equipment Section, covering trucks, tractors, tanks, mobile machine and repair shops, and allied matters. In December, 1918, he became vice-president of the Graves, Graff & Dresser Co., New York, and in August of the following year, he formed his own company, the Graff Engineering Corporation, New York, consulting engineers, specializing in design, investigations, and reports pertaining to industrial power, heat and illumination, and to the elimination of industrial waste by the improvement of manufacturing processes and equipment. He was president of the company until it was discontinued in 1931 when he became director of the Safety Engineering Division of the National Bureau of Casualty and Surety Underwriters.

Mr. Graff was elected a member of the A.S.M.E. in 1923. He served on the Society's Safety Committee from 1931 until his death, being a member the first three years, chairman two years, and advisory member the remainder of the time. He was the Society's representative on the Sectional Committee on a Safety Code for Walkway Surfaces from October, 1932, until his death. He had served since 1931 for the National Bureau of Casualty and Surety Underwriters on several other safety code committees. He was also a member of the Illuminating Engineering Society, Alpha Chi Rho fraternity, and the honorary society of Sigma Xi, and the Union Club of New Jersey. He had served as chairman of the Republican Committee in Westfield, N.J., where he made his home.

In 1913, Mr. Graff married Marjorie Higgins, and three children were born to them: Marian Barclay, Wesley Monteith, Jr., and Barbara Preston Graff.

ABBOTT DEAN GRANGER (1870–1938)

Abbott Dean Granger, president of the Granger Machinery Corporation, New York, N.Y., died at his home in Oakland, N.J., on September 27, 1938. Surviving him are Mrs. James S. (Peters) Granger, whom he married in 1895, and three daughters, Althea (Granger) Ross and Barbara S. Granger, of Ridgewood, N.J., and Olive (Granger) Oliver, of White Plains, N.Y.

Mr. Granger was born in New York on December 3, 1870, son of John Calvin and Althea (Dean) Granger. He attended high school in Brooklyn and secured a C.E. degree at the School of Mines, Columbia University, in 1892. For about eight years thereafter he was associated with Edwin Burhorn* in the firm of Burhorn & Granger, engaged in the installation and equipment of plants for power, heat, and electric light, and other contracting and engineering work. He then established the A. D. Granger Co., New York, and served as president of it and of its successor, in 1935, the Granger Machinery Corporation, until his death. The company designed, sold, and installed power plant machinery and other equipment.

Mr. Granger was elected a member of the A.S.M.E. in 1915 but accepted a loss in seniority in 1936 and is recorded as a member of that year. He belonged to the Columbia University Club and was at one time a member of the Brooklyn Engineers Club.

JOHN WILSON WISHART HALLOCK (1888–1937)

John Wilson Wishart Hallock, secretary of the General Alumni Association of the University of Pittsburgh, died on July 17, 1937, in the West Penn Hospital, Pittsburgh, Pa., after a long illness.

He was born at Pittsburgh on December 27, 1888, the son of Harvey T. and Ellen (Wishart) Hallock. He secured his preliminary education in the public schools of his native city, and then entered the University of Pittsburgh, where he was graduated with the B.S. degree in mechanical engineering in 1912, and in 1915 was granted the M.E. degree. In 1936 the degree of doctor of philosophy in economics was conferred upon him by the university.

From July, 1912, to October, 1913, he worked as assistant engineer for the Harris Pump & Supply Co., Pittsburgh, on the design, construction, and erection of hydraulic machinery. He was then employed for seven months as draftsman and junior engineer by the War Department, in the Engineer Depot, Washington, D.C. In June, 1914, he returned to the Harris firm in Pittsburgh, as assistant to the vice-president in executive and sales work. A year later he was engaged as instructor in cooperative work, by the School of Engineering, University of Pittsburgh, and subsequently became director of this work. An article by him entitled, "The Cooperative Plan of Engineering Education," published in the Bulletin of the Society for the Promotion of Engineering Education (vol. VIII, no. 1, September, 1917, pp. 12–24), describes the plan in some detail. In May, 1917, he began a term of active service with the U.S. Army, Corps of Engineers, entering as second lieutenant and being discharged, February 10, 1919, with the rank of captain in that corps. During the greater part of the time he was in charge of production districts for the General Engineer Depot. At the time of his death, he was colonel in the Corps of Engineer Reserves, and chief of the Pittsburgh Procurement District.

After leaving active service in 1919, Dr. Hallock resumed his former occupation as director of cooperative work in the University of Pittsburgh, but in October, 1919, he returned to the Harris Pump & Supply Co., as sales manager. However, about a year later he went back to the University of Pittsburgh as professor and head of the newly established Department of Industrial Engineering, in addition to resuming the directorship of the cooperative work; he also continued to act for the Harris Company in a consulting and sales organizing capacity. After eighteen years of active faculty service, Dr. Hallock was asked to take charge of the reorganization of the University's General Alumni Association. He became its secretary on August 1, 1933, and soon had it functioning. He took over this task when interest was at a low ebb, and built up its files of names and addresses from about 7,000 to more than 25,000.

He joined the A.S.M.E. as an associate-member in 1919 and was promoted to member in 1922. He was also a member of the Society for the Promotion of Engineering Education and the American Economics Association, of the national fraternity of Phi Gamma Delta, the Rotary and University clubs of Pittsburgh, the honorary

* For biography of Edwin Burhorn, see page RI-48.

fraternities, Sigma Tau and Omicron Delta Kappa, and of Scabbard and Blade, honorary military fraternity. He was a ruling elder in the Shadyside Presbyterian Church of Pittsburgh and general superintendent of the church school.

Dr. Hallock is survived by his widow, Mrs. Eva (White) Hallock, whom he married in 1914, and by two daughters, Janet Thomson and Eleanor Wishart Hallock.

He was the author of a number of published articles, principally on industrial safety, and of a widely known text, "Production Planning, Its Engineering Elements," published by the Ronald Press in 1929. In 1931 the outline of his work in industrial safety engineering was published by the National Safety Council and adopted as a standard text.

RUDOLPH K. F. HARTIG (1892–1937)

Rudolph K. F. Hartig, an engineer in the service of the Brooklyn Edison Company, Inc., died on June 9, 1937. Mr. Hartig was born at Waukesha, Wis., on March 24, 1892, the son of William and Fredrika (Dittman) Hartig, and obtained his preparatory education in the Waukesha public schools. He served in the U.S. Navy as a fireman, 1917–1919, and after the close of the World War entered Montana State College, from which he was graduated in 1925 with a B.S. degree in mechanical engineering.

From October, 1925, to July, 1927, Mr. Hartig was employed by the Brooklyn Edison Co., Inc., as junior engineer in power plant work, supervising the installation and maintenance of central station instruments. He also assisted in testing various equipment units, such as turbogenerators, condensers, boilers, stokers, and auxiliaries. In July, 1927, he was transferred to the main office of the Brooklyn Edison Co., where he was given charge of the preparation of reports and articles for A.S.M.E. and N.E.L.A. publications. He cooperated in obtaining and preparing data for a number of progress reports of the A.S.M.E. Special Research Committee on Condenser Tubes, 1927–1933, and prepared the N.E.L.A. Prime Movers Committee Serial Reports on Stoker Equipment and Furnaces, 1927–1928, and the Foreign Developments Report, 1929–1930. He also made plant betterment studies for the company.

Mr. Hartig joined the A.S.M.E. as an associate-member in 1930, and was automatically transferred to the grade of member in 1935. He served on the Annual Meeting Excursions Committee in 1929, 1930, and 1931, as chairman the last year.

In 1926, Mr. Hartig married Anna O'Hare of Brooklyn, N.Y., who, together with their two children, William J. and John G. Hartig, survives him.

PHILIP MOULTON HATHEWAY (1885–1937)

Philip Moulton Hatheway, of Brooklyn, N.Y., died at "Mowglis, School of the Open," East Hebron, N.H., on July 21, 1937. Mr. Hatheway was born in Boston, Mass., on October 19, 1885, the son of Amos L. and Cora L. (Moulton) Hatheway. He prepared for college at the Phillips Exeter Academy, from which he entered the Sheffield Scientific School of Yale University, being graduated from there in 1907 with a Ph.B. degree.

Following his graduation, Mr. Hatheway entered the employ of the Stanley Works, New Britain, Conn., where he worked in the office and cold rolled steel mill for about two years. He then served successively as field clerk, draftsman, and assistant engineer with Westinghouse, Church, Kerr & Co. He engaged in both inside and outside work in connection with various construction jobs and was connected with organization work at the main office of the company in New York, N.Y. In 1913, he went with the American Felt Company, Boston, Mass., as plant manager, remaining there until 1915, when he took a position with the Associated Factory Mutual Fire Insurance Company, Boston, making fire insurance surveys, inspections, and reports. In 1916–1917 he was connected with the International Steel & Ordnance Corp., Lowell, Mass., putting a detonator plant into production. The following year he was employed by the International Register Company, of Chicago, on war work. He acted as assistant to the president, directly connected with the manufacture and inspection of navy, ordnance, and signal corps matériel.

From 1918 to 1932, Mr. Hatheway was employed by the National Lead Company, of New York, N.Y. He was chief engineer at the Atlantic Works, Brooklyn, during the early part of the time, later becoming assistant superintendent of the plant, which position he held until he resigned in 1932.

Mr. Hatheway married Clitheroe James, of Brookline, Mass., in 1918, and is survived by her and their son Dean Moulton, and daughter, Clitheroe Dean Hatheway. Mr. Hatheway listed his recreations as canoeing and camping, and his hobby as photography; his religion as Congregational and his politics as Republican. He was a member of the Yale Club of New York, Appalachian Mountain Club of Boston, and the Masonic fraternity. He joined the A.S.M.E. as a junior in 1913, and was promoted to the member grade in 1921.

CHARLES GILBERT HAWLEY (1868–1939)

Charles Gilbert Hawley, lawyer, scientist, and internationally known inventor, son of the inventor, Benjamin Ruggles Hawley, and Rosamond (Hall) Hawley, was born in Normal, Ill., on June 20, 1868. His parents were early Illinois pioneers.

Mr. Hawley's early schooling was in Chicago, Ill. He attended Cornell University for his academic work and took his graduate work at Northwestern University, from whose Law School he received the Bachelor of Laws degree on June 11, 1890. He immediately entered the active practice of the law, specializing in all branches of patent law. Because of his keen inventive analytical mind he rose rapidly and was in great demand by prominent corporations who recognized his great ability as both technical adviser and trial expert. In the beginning of the century he moved his offices from Minneapolis, Minn., where he started his practice, to Chicago, where he had his headquarters, but divided his time between his offices there and in New York and Washington. He kept his legal residence in Chicago until January, 1938, when he changed it to Cleveland, Ohio.

One of Mr. Hawley's early associations was as counsel and large shareholder of the Universal Rim Company, who owned the patents on the Baker demountable rim, the first demountable rim on the market. He was also one of the first inventors to conceive the idea of the front-wheel drive for automobiles, but did not push it because of his belief that it was too far in advance of the industry to be at that time profitably marketable.

Mr. Hawley was an officer and large stockholder of the Locomotive Fire Box Company, who manufactured and marketed, under patents assigned to it by Mr. Hawley, the Nicholson thermic syphon, used by more than one hundred railroad companies in this and foreign countries. He severed his connections with this company a few years ago, after which he took out domestic and foreign patents on an improved downflow thermic syphon, which patents he assigned to the Downflow Syphon Company, of which he became an officer, large stockholder, and technical adviser. This new syphon is now being marketed by this company.

In 1924 Mr. Hawley organized and became president of Centrifix Corporation, with headquarters in Cleveland. This company manufactures and markets outstanding high-efficiency centrifugal separators and purifiers for the removal of solids and other objectionable entrainment from steam, gas, air, and vapor. Through Mr. Hawley's ingenious inventions this company also developed high-speed tar extractors, fractionating units, and gas scrubbers of a standard of efficiency equal to that of his purifiers. During the time Mr. Hawley was directing head of Centrifix Corporation, a position he held until his death on April 16, 1939, he invented, perfected, and assigned to this company eighty-six United States patents and a great number of foreign patents under which the company now operates. The basis and most remarkable part of these inventions is that none of the equipment has any moving parts, which makes them of lifelong duration.

During the last fifteen years of his life Mr. Hawley spent much of his time in the development of a new type of sewage treatment plant. His main aim in this was to be able to give to the public at a very low cost a complete sewage treatment apparatus that required little space, is easily installed, operates at a minimum operating cost, and is easily added to if necessary. These plants were designed especially for small communities which in the past have been denied the benefits of sewage treatment because of the costs involved. The Hawley Engineering Company has taken up where Mr. Hawley left off and is carrying forward his ideas for the further development and marketing of these sewage disposal plants. The future development of these plants is based upon patents granted or applied for by Mr. Hawley during his life.

Mr. Hawley had been a member of the A.S.M.E. since 1926. He also belonged to the Masonic fraternity.

Mr. Hawley was an individualist of the old school. He was a man of force and indomitable will, but endowed with a big heart and a loyalty to his friends which was unshakable. His friends and those who knew him loved and respected him and have deeply mourned their loss. His work and his family occupied all of a full, successful, and praiseworthy life. His death brought to him a well deserved rest—a rest he did not have time to take during his life.

Mr. Hawley is survived by his wife, Virginia (Taylor) Hawley, and three children, Hope (Hawley) Degenhardt, John Stuart Hawley, and Charlotte (Hawley) Laier.—[Memorial prepared by RANDALL T. ELLIOTT and HUBERT H. RICHARDSON, Cleveland, Ohio, nephews of Mr. Hawley.]

ROBERT THOMPSON HAZELTON (1883–1937)

Robert Thompson Hazelton, secretary-treasurer of The Cincinnati Shaper Company, died suddenly of thrombosis on March 3, 1937, in Cincinnati, Ohio. Mr. Hazelton was born in Petoskey, Mich., on July 17, 1883, the son of Wilbur and Margaret (Patterson) Hazelton. He obtained his early education in the public schools of Petoskey, and Medina and Rochester, N.Y. He also attended the Rochester Business Institute for one year; took a four-years' course in the Mechanics' Institute of Rochester, covering such subjects as are usual in a course in mechanical engineering; and served an apprenticeship as a machinist at the A. L. Sweet Iron Works, Medina, working on general manufacturing, tools, and jigs. During the summer of 1901 he worked in the drafting room of the A. L. Sweet Electric Light & Power Co., manufacturers of motors and other electrical apparatus.

In October, 1901, Mr. Hazelton entered the employ of Charles Bridgeford, Rochester, N.Y., manufacturer of machine tools and special machinery, and spent about six months there on shop work. Later he designed and patented the line of machine tools built by the Bridgeford Machine Tool Works, of Rochester, which company was successor to Charles Bridgeford. Here he had charge of drafting and design, and specialized in designs for jigs and fixtures used with the machine tools manufactured by the company.

Mr. Hazelton did special work at the University of Rochester in 1909, and then returned to the Bridgeford Machine Tool Works as superintendent. In March, 1911, he was engaged by the Cincinnati Milling Machine Company, on supervision of tools; in 1914, he was made head of the Engineering Department; in 1915, works manager and chief engineer. In June, 1920, Mr. Hazelton became works manager of The Cincinnati Shaper Company and was made treasurer in 1927. While at The Cincinnati Shaper Company he developed a line of machine tools and sheet metal working equipment; these machines today are recognized leaders in their particular fields.

He joined the A.S.M.E. as a junior in 1909, and was promoted to member in 1916. He served from September, 1929, to October, 1936, on Subgroup No. 7 on Gear Cutting and Hobbing Machines of Technical Committee No. 4 on the Standardization of Spindle Noses and Collets for Machine Tools of the Sectional Committee on the Standardization of Small Tools and Machine Tool Elements. He was also a member of Technical Committee No. 1 on T-Slots of the Sectional Committee on the Standardization of Small Tools and Machine Tool Elements from September, 1924, to the date of his death, representing the National Machine Tool Builders' Association. Mr. Hazelton was an active member of the committee appointed in 1931 by the Industrial Commission of Ohio to study and to develop better means for the safeguarding of metal-working machinery.

Mr. Hazelton was director of the Engineers' Club of Cincinnati for several years. He also belonged to the Cincinnati Club, the Hyde Park Country Club, and the Masonic order. He was twice married; his first wife, Miss Rose Westcott, predeceased him. His second wife was Mrs. Lydia Jenkins, by whom he is survived, as well as by three children: Mrs. Rupert Benson of Camp Hill, Pa.; Burton Hazelton, of St. Louis, Mo.; and Merrill Hazelton, of Cincinnati, Ohio.

NATHANAEL GREENE HERRESHOFF (1848–1938)

Nathanael Greene Herreshoff, retired president of the Herreshoff Manufacturing Company, died at his home in Bristol, R.I., on June 2, 1938, after a year's illness. At the time of his death Mr. Herreshoff was ninety years of age.

While famous primarily for his achievements in the field of yacht design, which gained for him among yachtsmen the name "Wizard of Bristol," Mr. Herreshoff had to his credit many noteworthy accomplishments in mechanical engineering, which led to his election to honorary membership in the A.S.M.E. in 1921.

Mr. Herreshoff was born in Bristol, R.I., on March 18, 1848, the son of Charles Frederic and Julia Ann (Lewis) Herreshoff. He received his early education in the public schools of Bristol and his advanced technical training at Massachusetts Institute of Technology, which he attended from October, 1866, to May, 1869. He was awarded the honorary degree of Master of Science in 1896 by Brown University, a recognition peculiarly fitting, in consideration of the fact that his great-grandfather, John Brown, was the founder of that institution.

Upon completion of his education, Mr. Herreshoff joined the Corliss Steam Engine Company of Providence, spending nine years with that organization, first as draftsman, later engaged in engine adjusting, and finally in charge of steam and hydraulic engineering, particularly in connection with the development of large pumping engines. While with the Corliss company one of his most important responsibilities was the conduct of experiments and the testing of material for the construction of the famous engine which furnished the motive power for the Centennial Exposition in Philadelphia in 1876. Mr. Herreshoff was also in charge of the installation of this engine, starting it, and conducting power tests. During this period in his career as one of the pioneers in the design of compound steam engines, he was awarded two patents on steam engine governors.

The Herreshoff Manufacturing Company of Bristol was founded in 1863 by Mr. Herreshoff's older brother, John Brown Herreshoff, who remained at the head of the concern until his death in 1915. Nathanael Herreshoff's interest in boats dated from the early years of his youth on the shores of Narragansett Bay, for it is reported that at the age of ten he designed and built a twenty-foot catboat, the forerunner of the series of fast sailing yachts which made his name known throughout the yachting world. While still connected with the Corliss company he did a certain amount of designing for his brother John, hence it is not surprising that in 1878 he joined the Herreshoff company as designing engineer and superintendent of construction. After the death of his brother, Mr. Herreshoff became president of the company, serving in this capacity until 1925 when the concern was reorganized and he retired.

During its early years the Herreshoff Company was engaged in the construction of sailing vessels, but in the 1870's its interest turned to the production of fast steam-driven craft, Nathanael Herreshoff's knowledge of steam power playing a large part in its success. In 1876 he designed the first torpedo boat for the United States Navy, the boiler being designed by his brother James. The success of this craft led to the receipt of orders for many similar vessels from several foreign governments. During this period Mr. Herreshoff was awarded several patents on details of construction of steam engines, and perfected the design of coil boilers for use on steam yachts and other fast steam-powered vessels. His ingenuity in the reduction of unnecessary weight in power plants became evident at this time, and his engineer's craving for efficiency in design carried over into his later work with fast sailing yachts. The fundamental soundness and advanced character of his designs may be appreciated when it is realized that many winches and other devices designed by him were still in use on *Ranger*, the last America's Cup Defender, sailed in 1937.

In the late 1870's Mr. Herreshoff began his experimenting in the field of fast sailing yachts, the field in which he was preeminent until his retirement. Probably the first of his creations to cause excitement in yachting circles was *Amaryllis*, a double-hulled sailing catamaran built in 1877, which showed remarkable speed and led to arguments among racing committees of that day. This craft was followed in 1891 by *Gloriana*, a boat which may be said to have truly revolutionized the design of racing yachts, since she was the first to embody such features as the spoon bow and long overhangs which gave the yacht a greatly increased sailing length when heeled. *Gloriana's* phenomenal speed and racing success, together with that of *Wasp*, built in the following year, brought the designer to the attention of the yachtsmen of this country and led to the production of a long line of yachts which were to make international yacht-racing history.

In 1893, when another challenge for the America's Cup was received from England, Nathanael Herreshoff was in the front rank of American yacht designers, and it was inevitable that he should be called upon to design a defender. He produced *Vigilant*, which defeated Lord Dunraven's *Valkyrie II* in three straight races. This success was followed by *Defender*, which defeated *Valkyrie III* in 1895 and by *Columbia* which defeated the first of Sir Thomas Lipton's *Shamrocks* in 1899 and repeated against *Shamrock II* in 1901. The long series of Herreshoff defenders was completed by *Reliance* in 1903 and *Resolute* in 1920, these two defeating Lipton's *Shamrocks III* and *IV*.

In 1925 the Herreshoff Manufacturing Company was reorganized and Nathanael Herreshoff retired from active participation in the business. The company, however, continued its connection with the defense of the America's Cup, for *Enterprise* and *Rainbow*, the successful defenders of 1930 and 1934, were built at its Bristol plant from designs by W. Starling Burgess. Mr. Herreshoff continued his active interest in yachting and yacht designing as long as his health would permit, his last design being the yawl *Belisarius*, which he designed for Commodore Carl B. Rockwell of Bristol in 1935.

On March 18, 1938, the Town Council of Bristol took note of Mr. Herreshoff's ninetieth birthday by the passage of a testimonial resolution which evidenced the high esteem in which he was held by his fellow citizens. This resolution testified in part that "by his extraordinary talents and genius for marine architecture—by his sterling character and integrity, by his interest in Bristol both as a just and fair employer and as a worthy citizen, extending over an unusual period of years, he has endeared himself to our people and brought renown upon his native town, placing our citizens under lasting obligations to him."

While Mr. Herreshoff's fame depended chiefly upon his achieve-

ments as a designer of racing yachts, his accomplishments as an engineer in steam power plant development would in themselves have made his career of importance. His genius lay in the combination of accurate science with the less definite characteristics of art which has marked the great designers in all fields.

In addition to his honorary membership in the A.S.M.E., Mr. Herreshoff was also a member of The Society of Naval Architects and Marine Engineers, The Franklin Institute, and the Institution of Naval Architects of London.

Mr. Herreshoff was married in 1883 to Clara A. DeWolf, who died in 1905. In 1915 he married Ann R. Roebuck, who survives him. Surviving him also are four sons: A. Sidney of Bristol, A. Griswold of Grosse Pointe, Mich., L. Francis of Marblehead, Mass., and Clarence DeWolf of Bristol; also one daughter, Miss Agnes M. Herreshoff of Bristol. Of the sons, A. Sidney and L. Francis are following their father's career of naval architecture.—[Memorial prepared by Z. R. Bliss, Providence, R.I., Mem. A.S.M.E.]

ED HILL (1876–1937)

Ed Hill, superintendent of the City Water and Light Plant, Jonesboro, Ark., died on July 17, 1937.

Mr. Hill was born at Olney, Ill., on May 4, 1876, the son of Kizziah and Edward F. Hill. He attended the Olney schools and in 1890 entered the service of the Olney Edison Electric Light Company, as apprentice operating engineer. He remained in Olney until 1895, when he went to Flora, Ill., as assistant foreman on the construction of a power plant, of which he subsequently became operating engineer.

He was employed from 1900 to 1904 by the St. Louis-San Francisco Railway Company, at Springfield, Mo., on field construction work. He then became lineman for the City Water and Light Plant of Jonesboro, for which he later served as chief engineer, and subsequently superintendent in charge of construction, operation, and maintenance of plants, which position he was holding at the time of his death. Mr. Hill was largely responsible for the design, construction, and equipment of the present Jonesboro power plant.

Mr. Hill became a member of the A.S.M.E. in 1932. He married Miss Kate Galbraith, of Flora, Ill., in 1899, and is survived by her and one daughter, Helen (Hill) Roth.

GEORGE N. HINCHMAN (1866–1937)

George N. Hinchman, of Webster Groves, Mo., died on May 25, 1937. At the time of his death, Mr. Hinchman was engineer in charge of development and design for Otto Eick, Inc., of St. Louis, Mo.

He was born on March 17, 1866, at St. Louis, the son of George Nichol and Elizabeth (McFarland) Hinchman. He obtained his elementary education in the grade schools of St. Louis, and was graduated in 1884 from Washington University, in mechanical engineering. He served as an apprentice from 1884 to 1886 in the Standard Foundry Company of St. Louis, and from 1886 to 1890, under Charles K. Pickles, of St. Louis, learning drafting and machine design.

From 1890 to 1899, Mr. Hinchman was in charge of drafting and design for the Falls Rivet & Machinery Co., Cuyahoga Falls, Ohio, and as their engineer was responsible for all plant layouts and designs made by that firm. In 1899, he went to the Pittsburgh Meter Company, East Pittsburgh, Pa., and was in charge of design, special inspection, and erections. He returned to St. Louis in 1902, as designer and experimental engineer for the Standard Adding Machine Company. He was superintendent of the Compressed Air & Vacuum Machinery Co., St. Louis, in 1910–1911, and then until 1918 was employed by Otto Eick, a brewery engineer, designing and erecting bottling machinery. Subsequently he was connected with the Alvey Manufacturing Company, St. Louis, designing elevators and conveying machinery, and with the Wagner Electric Company, St. Louis, designing airplane motors for the United States government.

From 1922 to 1928, Mr. Hinchman was in charge of the Maintenance Department of the Commonwealth Steel Company, Granite City, Ill., where he was responsible for all construction designs. From 1928 to 1932, he was employed to handle all special design work for the W. W. Sly Manufacturing Co., Cleveland, Ohio, and in 1932, he returned to Otto Eick, Inc., as engineer in charge of all development and design, which position he held up to the time of his death.

Mr. Hinchman became a member of the A.S.M.E. in 1919, and was also active in the Masonic order in Webster Groves and Cleveland. He married Elizabeth Scown in 1890 and they had one daughter, Laura, now Mrs. R. R. Johnson, of Dallas, Texas.

CLARENCE FLOYD HIRSHFELD (1881–1939)

Clarence Floyd Hirshfeld was born in San Francisco, Calif., on January 30, 1881, and received his elementary education in the public schools of that city. It was his early ambition to be a mining engineer but he grew away from this and in 1898 entered the University of California to study electrical engineering. Graduating in 1902 with the degree of bachelor of science in electrical engineering, he entered Cornell University in 1903 as a graduate student in mechanical engineering and received the degree of M.E. in 1905.

During his first year at Cornell, Dr. Hirshfeld became an instructor in experimental engineering and advanced in the following years to the positions of assistant professor and finally professor of mechanical engineering, teaching successively experimental engineering, heat power engineering, gas engine design, gas manufacture, and gas distribution. He remained a member of the faculty until 1914 and was author and co-author of several textbooks, including:

Engineering Thermodynamics, 1913
Farm Gas Engines (with T. C. Ulbricht), 1913
Steam Power (with T. C. Ulbricht), 1913
Elements of Heat Power Engineering (with W. N. Barnard), 1915
Economic Operation of Steam-Turbo-Electric Stations (with C. L. Karr), 1918
Elements of Heat Power Engineering (with W. N. Barnard and F. O. Ellenwood), Latest Edition, 1933.

Early in his teaching career, Dr. Hirshfeld undertook a private consulting practice which grew to wide proportions and broad scope. In 1913 he was engaged by Alex Dow, president of The Detroit Edison Company, for consulting services in connection with that company's power system. He became active in many phases of the company's business, notably in the field of industrial electric heating, and in 1914 resigned from Cornell to become chief of research for The Detroit Edison Company under an arrangement which provided for the continuation of his private consulting work.

In addition to his duties as research adviser to the management, Dr. Hirshfeld organized and headed the company's Research Department, credited as being one of the first of its kind in an electricity supply company, and one now widely known in this country and abroad for its pioneering in many fields, the high quality of its work, and its many contributions to the art. As an essential part of the department, Dr. Hirshfeld organized and developed the company's library, which is outstanding of its kind and which has served as a model for many other organizations. Continuing with the company until his death, Dr. Hirshfeld has left many marks of his work, his influence, and his inspiration. He had an active part in the design of power plants, the development of scientific purchasing methods, the institution of an inspection division, the development of standardization practices, the establishment of patent policies, and the general development of the research attitude throughout the organization.

He was called into the service of the War Department late in 1917, and was first commissioned as major in the U.S. Army Ordnance Department and later as lieutenant-colonel. His previous engineering training made him immediately available for the task in hand, that of general supervision of the inspection of artillery and artillery ammunition purchased for the army. He forthwith devoted himself with characteristic energy to the effective administration of inspection forces quickly organized for the war effort and drawn largely from civilian life. Shortly after his entrance upon this work, the inspection section of this departmental division was decentralized by the establishment of district ordnance offices and it became Dr. Hirshfeld's duty to act as liaison officer between the several districts and the headquarters in Washington. He served in this capacity with marked intelligence and undoubted distinction until he was honorably discharged in May of 1919. He returned then to his place in the Detroit Edison organization, from which he had been given temporary leave, and resumed the activities interrupted by the war service.

As in many other cases where men had similar experience in war materials procurement, Dr. Hirshfeld continued his interest in ordnance work through membership in the Army Ordnance Association. During the last four years of his life he was assistant chief of the Detroit Ordnance District, his knowledge of the subject, based upon experience in time of actual war, making his counsel invaluable.

In various associations of the electrical operating industry Dr. Hirshfeld was a prominent figure. He served as member, and more often as chairman, of many committees of the National Electric Light Association and in 1926 he was made chairman of the National Technical Section, one of the four major divisions of the organization. Likewise he was active on many committees of the Association of Edison Illuminating Companies, notably the Committee on Power Generation and the Committee on Electric Switching and Switchgear, which he headed in 1928 at the time of its organization. He was representative for several years of the electric light and power group on the American Engineering Standards Committee and its successor, the American Standards Association, and he served as a member of the United States National Committee of the International Electrotechnical Commission.

Under the auspices of the Association of Edison Illuminating Companies, a conference of electric utility executives and research men was held in 1933 to discuss the feasibility of a joint research organization of electric operating companies. The result of the conference was the formation of the Edison Research Coordinating Council, of which Dr. Hirshfeld was made vice-chairman and later chairman. He served also as chairman of the council's research committee on metallurgical applications of electricity. When the council was later incorporated under the name, Utilities Coordinated Research, Inc., he was elected president.

Although an active member of many technical and professional organizations, Dr. Hirshfeld was most prominent in The American Society of Mechanical Engineers, of which he became a junior member in 1905, member in 1919, and Fellow in 1936; to which he contributed many outstanding technical papers; and of which he was an officer and member of the Council as a manager from 1929 to 1932 and as vice-president from 1932 to 1934.

His early work in the Society dealt largely with standardization, test codes, and special research projects. For many years he served as a member of the main Power Test Codes Committee, counseling it on the broad aspects of acceptance tests, and as chairman of the individual committee dealing with instruments and apparatus he rendered both the committee and the Society extremely valuable and efficient service.

More recently he was actively concerned with the professional training and development of the engineer. In 1928 he became a member of the Committee on the Economic Status of the Engineer, which sponsored the study on earnings of engineers for the year 1930 and later recommended the steps which led to the formation of the Engineers' Council for Professional Development. Dr. Hirshfeld served as chairman of the preliminary organization committee of E.C.P.D. and for two years as first chairman of that body. He exerted a valuable influence in its formative years by his clear concept of the ideals of the new organization and by the selection of men of vision and understanding to carry on its work. After his retirement as chairman he remained an active member of the E.C.P.D. until his death.

Dr. Hirshfeld's full appreciation of the need for providing orderly access to technical literature led to his active support of The Engineering Index, on the Advisory Board of which he represented The American Society of Mechanical Engineers, and to his devoted service as a director when it became a separate undertaking as Engineering Index, Incorporated.

Other organizations of which Dr. Hirshfeld was a member included the American Institute of Electrical Engineers, American Association for the Advancement of Science, American Chemical Society, American Institute of Mining and Metallurgical Engineers, American Society for Testing Materials, Econometric Society, The Newcomen Society, Sigma Xi, and the Princeton Engineering Society.

An able lecturer and finished public speaker, Dr. Hirshfeld gave generously of his time in filling demands for his appearance on programs of technical, professional, and industrial organizations. He addressed sales conferences, educators, purchasing agents, operating men, and executives with the same skill that made him a great teacher, for he possessed an outstanding ability to convey new and complex subject matter in such unique and interesting fashion that his listeners absorbed it without conscious effort. In 1932 he delivered the commencement address at Rensselaer Polytechnic Institute which at that time honored him with the degree of Doctor of Engineering; in 1935, under the auspices of Science Service, he gave a radio broadcast on the subject of Science in Transportation, and in 1936, the Brackett Lecture on Industrial Research at Princeton University. A prophet not without honor in his own country, he received the degree of Doctor of Engineering from the University of Detroit in June of 1938.

Dr. Hirshfeld was well known in America and Europe as the author of scientific and engineering papers and articles. He wrote extensively on the many phases of electricity supply business and his writings on engineering education, professional training, and the place of the engineer in society won nation-wide comment and praise. In 1934 his paper, "Engineers of the Next Generation," won the American Institute of Electrical Engineers' national prize for the best paper on public relations and education, and he was the recipient of the Worcester Reed Warner Medal at the Annual Meeting of The American Society of Mechanical Engineers in December, 1937. He was also author of the paper, "Preparation and Combustion of Fuel," read before the First World Power Conference in London, 1924, and "Research Relating to Power Development," before the Second World Power Conference in Berlin. In 1926 his paper, "What Is the Demand for Overload in the U.S.A.?" was presented before the International Electrotechnical Congress. He was author of the chapter, "The Spirit of Power," in the composite book, "Toward Civilization," edited by Dr. Charles A. Beard and published in 1930.

Gaining recognition first as an educator, Dr. Hirshfeld later became known as one of the world's leading figures in the field of industrial research. Early in life he adopted what he termed "the research method of thought," and his naturally inquisitive mind, his remarkable powers of observation, and an enviable memory, contributed to the ultimate development of that type of mental approach to a high degree of perfection. He applied it not only to consideration of phenomena in the physical world but to the behavior of human beings as well. He cautioned against living in the present without knowledge of the past and appreciation of the possibility of the future, and he taught the intelligent use of known and procurable facts in the solution of problems of all types, whether scientific, industrial, civic, economic, or social.

One of his greatest achievements was the ability to assemble, rationalize, and coordinate facts and knowledge of all kinds into a single pattern which he referred to as "the whole scheme of things." Even the obscure and apparently unimportant observations found their place in that pattern. To him, that which divides knowledge into different classes was merely a matter of terminology; in all he saw the same elements, the same forces, and the same behavior under comparable influences, so that he interpreted all experiences by a single set of laws.

He often referred to research as merely a fact-finding process, but those who knew him realize it was his ability to interpret the significance of new and often apparently unimportant facts in terms of already existing knowledge that made him outstanding as a research engineer. He possessed a fertile imagination and the necessary courage to venture on new lines of thought even though they might lead along untraditional paths and run contrary to conventional belief and practice. It was probably this attitude of mind, together with his connections with many research undertakings, that led to his service on the Advisory Board of the Purdue Research Foundation; the National Board of Councillors of the United States Bureau of Mines; the Ohio State University Research Foundation; the National Research Council; and the American Institute of Physics' Advisory Council on Applied Physics.

In 1930 a committee of street railway executives, known as the Electric Railway Presidents' Conference Committee, was organized to deal with an acute situation which had arisen in their industry. Increasing competition of the rubber-tired, automotive type of vehicle had reached such proportions that fear was expressed for the future existence of the electric street car, and the huge investment in street railway properties throughout the nation appeared seriously jeopardized. Despite certain advantages of the rail-type vehicle in mass transportation and despite miscellaneous efforts to modernize it, the street car lacked the public appeal offered by its competitors. Recognizing that the electric car had developed largely along traditional lines by rule-of-thumb methods, whereas its competitors had grown out of the great mass of scientific research that forms the background of the automotive industry, the committee was aware that a street car capable of recapturing public favor must be more than simply the old mechanism in a new dress; it must be a new product of scientific effort under the most able direction available. The choice of Dr. Hirshfeld for the task stands as a great tribute and a fine expression of the confidence in this man who had had no experience in the field of transportation and had not been identified with this branch of engineering.

He was appointed chief engineer of the committee in the fall of 1930 and immediately started an analysis of the problem. In this he conferred not only with street railway executives, engineers, and operators, but in characteristic fashion with factory hands, office workers, and housewives who made use of public means of transportation. He diagnosed the shortcomings and found the need for many improvements, but there was available little information as to the specifications to be met, or the inherent possibilities and limitations of a rail vehicle.

Accordingly Dr. Hirshfeld set up a program of research and experimentation, established a laboratory, and employed a group of engineers and technicians to work under his direction in a fundamental study of the whole problem of street car design and performance. After four years of intensive activity, an initial car was produced containing many revolutionary developments in truck design, wheel construction, control equipment, lighting, ventilation, and body. Steel springs had given way to rubber springs, the wheels contained rubber disks insulating the steel rim from the rest of the structure, and other novel features had been successfully developed and applied. A rail vehicle had been created which could equal or outperform the modern automobile in accelerating or braking rates. The smoothness of ride by actual test excelled that of any other street vehicle, and the noise level had been reduced to a point where the "sing" of the trolley wire became the distinguishing evidence of the car's approach. A new type of welded body with modern lines and appearance, heated, lighted, and ventilated by improved methods,

constituted the new dress in which this revolutionary street car made its appearance.

Exhibited at the Cleveland Convention of the American Transit Association in September, 1934, the new car met with enthusiastic approval of the street railway industry. It was called the Presidents' Conference Committee Street Car and is now commonly known as the P.C.C. car. When commercial production was undertaken, the committee's interests were transferred to the newly incorporated Transit Research Corporation. Dr. Hirshfeld continued as chief engineer of the new organization until the time of his death.

That the P.C.C. car has met with public favor is evidenced by the fact that at the end of 1939 there were approximately 1130 cars of this type in operation or under construction for thirteen cities in the United States and Canada.

Teacher, scientist, engineer, lecturer, and always a scholar; it would seem that such achievements and accomplishments must have completely filled a comparatively brief life span of 58 years. Yet, Dr. Hirshfeld took time to listen to those who brought their individual problems to him; to encourage them in the development of worthwhile ideas; and to divert their misdirected efforts to more logical ends. His instant recognition of the best in those with whom he came in contact, his deep understanding and broad tolerance of humanity's shortcomings, and his desire, without a trace of the overzeal of the reformer, to make the world a better place for his having lived in it, won respect, admiration, and genuine affection from his great circle of friends.

His casual observation and his more considered advice were sought by his neighbors and friends who valued the honesty and integrity of his opinion, while those privileged to know him more intimately not only appreciated his good humor and innate modesty but found in him the love, devotion, sincerity, and hospitality which added so much to the realization of an unusually happy home life.

In addition to the recognition which was his, living, it is fitting that this final honor, the award of the John Fritz Medal, should have come to him. There could be no finer memorial than the words of the citation, "for notable leadership through research and development in power generation and electric traction and for being a great teacher and friend of man, young and old."

Dr. Hirshfeld's death occurred on April 19, 1939, at the Grace Hospital in Detroit, after an illness of several months. Surviving him are his widow, the former Elizabeth Bishop Winslow, of Ithaca, N.Y., and two sons, John W. and James F. Hirshfeld.—[Biography, slightly expanded, prepared by F. DOUGLAS CAMPBELL, personal assistant to Dr. Hirshfeld at The Detroit Edison Company, for the John Fritz Medal Board of Award.]

JAMES DAVID HOFFMAN (1868–1938)

James David Hoffman, affectionately known as "Jimmie" by his many friends, a member of the engineering staff of Purdue University from 1890 to 1911 and from 1917 to 1938, died at midnight on Saturday, August 13, 1938, at his home in West Lafayette, Ind. He was born in Auburn, Ind., on January 23, 1868, son of Daniel Zinn and Rachael C. (Goetschius) Hoffman. He is survived by his widow, Zoelah M. (Burroughs) Hoffman, whom he married in 1913, and by one son, James David Hoffman. His first wife, Kate B. (Peterson) Hoffman, whom he married in 1890, died in 1902.

Professor Hoffman served as apprentice machinist with the Auburn Foundry and Machine Works between the time he was graduated from the Auburn High School in 1883 and his entrance to Purdue University in 1886. He was graduated from Purdue University with the degree of B.M.E. in 1890, and the degree of M.E. was conferred upon him in 1893. During the summer of 1890 he was draftsman and designer for the Buckeye Engine Company at Salem, Ohio, but was recalled the same fall to Purdue University to the post of assistant in practical mechanics, working under the direction of the late Dean W. F. M. Goss. He was promoted to the rank of instructor in 1891 and to assistant professor in the same department in 1901. In 1902 he was appointed assistant professor of machine design at Purdue University and was promoted to associate professor in 1903 and to professor in 1908. His connection with Purdue University was interrupted from 1911 to 1917, when he held the position of professor of mechanical engineering and practical mechanics at the University of Nebraska. He was recalled to Purdue University in 1917 to the position of professor and head of the department of practical mechanics, as successor to Michael Joseph Golden. Since 1929 he had also been in charge of the curriculum of industrial education. Professor Hoffman was retired from active service at Purdue University with the rank of professor-emeritus, effective September 1, 1938.

He was author or co-author of a number of books on engine and boiler design, machine design, and heating and ventilating; also of five pamphlets on house construction and heating of homes. His contributions to the technical press included numerous articles and papers, published in technical magazines and in the transactions of engineering societies.

In addition to the courses which he taught at Purdue University and at the University of Nebraska, Professor Hoffman delivered frequent nontechnical lectures and radio talks on residence construction, heating and ventilating, and shop practice.

His society affiliations included the following: The American Society of Mechanical Engineers (junior 1894, member 1903), American Society of Heating and Ventilating Engineers (life member and past-president), National District Heating Association (honorary member), National Warm Air Heating and Air Conditioning Association (honorary member), Warm Air Furnace Code Committee (first and only chairman from its organization in 1921 until his death), Society for the Promotion of Engineering Education (life member), Executive Committee, Central Indiana Section, A.S.M.E., Indiana Engineering Society, Advisory Committee for the Indiana Federal Housing Administration, Tau Beta Pi, Sigma Xi, Sigma Tau, Kappa Delta Rho, Rotary International (past-president, Lafayette Rotary Club). He was also an active member of the Presbyterian Church at Lafayette, Ind., and at Lincoln, Neb., having served on all of its official boards. He was a public-spirited citizen and as such devoted himself unselfishly to his community and state.

An editorial appearing in the Lafayette *Journal Courier* of August 14, 1938, reviewed his life and work in the following manner:

"With the passing of Professor James D. Hoffman, another of the sturdy, mature dependables who helped make Old Purdue a power in education, disappears from the campus he graced for so long. Professor Hoffman had been retired at seventy but he was to continue to have an office on campus, and had been awarded emeritus honors.

"Activity, hard work and constant association with youth had kept Professor Hoffman young in heart and spirit. He was a jolly companion, a good and cheery neighbor, a splendid citizen, a successful and greatly beloved teacher. Perhaps he was best described as 'a Christian gentleman.'

"His practical helpfulness in his relations with the young, over and above the functions of a teacher, have been attested many times. He knew how to be helpful when help was really needed, and there was no ostentation in his well-doing. His influence on behalf of clean living and integrity was far beyond that of a mere professor. His simplicity and sincerity, his friendliness and unassuming guidance by example rather than preachment, made him a real power in college, community, club and church, among young and old alike. 'Jimmie' Hoffman leaves a vacancy in the ranks of sound civic life and better education which it will be hard to fill."—[Memorial prepared by L. V. LUDY, Lafayette, Ind., Mem. A.S.M.E.]

JOHN A. HUNTER (1868–1939)

John A. Hunter entered this world at Stormstown, Pa., on May 15, 1868, son of John A. and Elizabeth (Elder) Hunter. By way of contrast, the word "storm" had no place in the tranquil life which he was destined to live. His bland sense of humor, his ability to appreciate the other fellow's point of view, and the basic spirit of fair play which dominated his life, left him unusually free of enemies and from the normal strife of life. He did not avoid making adverse criticisms, but such criticisms were usually accompanied by helpful suggestions and with a crack of humor which defied resentment. He seemed to anticipate friction between human beings and his efforts to maintain peace and goodwill were successful to an amazing degree.

After graduating from Pennsylvania State College in 1890 with the degree of B.S. in mechanical engineering he spent three years teaching manual arts in Georgia. He then took graduate work at Cornell University and Pennsylvania State College, where he gained an M.E. degree in 1896. He was an instructor and assistant professor of mechanical engineering there from 1894 to 1904 and then went to the University of Colorado as an assistant professor. Two years later he was made a full professor and placed at the head of the department of mechanical and chemical engineering, a position he continued to hold until reaching the retirement age.

Professor Hunter's humor and friendly smile were appreciated as fully by the women students in the university as by the men. One day Professor Hunter entered a dining room during a rather furious "boarding house" debate when one of the girls flew to his side in an appeal for support and called him "Uncle John." This girl is now the wife of Alvin Forbess, chief engineer for the Amalgamated Sugar Company of Utah. There was a significance to this little episode which became a characteristic part of the remaining twenty-five years of Professor Hunter's life. Not only did he become "Uncle John" from then on to every acquaintance from the governor of the state down to the boy in the streets, but through the use of that simple and affectionate salutation, "Uncle John," all barriers were

down and future hundreds were destined to do as Mrs. Forbess had done—fly to his side for advice, comfort, and protection.

John Hunter had a keen political mind and this ability was soon recognized by the president of the university. For many years the president sought his advice on political affairs affecting the university. Professor Hunter also persuaded many of the best regents ever to serve on the board that it was their duty to make the necessary sacrifice and seek election to this non-salaried position. Professor Hunter also contributed his own efforts to the cause of public government and civic interests. He was a member of Boulder City Council from 1912 to 1916. He served the Chamber of Commerce as president during 1923, 1924, and 1925. He was president of the Boulder Club over a long period of years. He headed many campaigns, such as community chest, etc., and he was rightfully considered one of the leading citizens of Boulder.

From 1896 until 1918 Professor Hunter spent his vacations in the employ of such firms as Westinghouse Machine Company, Pittsburgh Locomotive Works, Baldwin Locomotive Works, and the Pennsylvania Railroad, and his practical knowledge was one of his greatest assets.

He searched continuously for employment opportunities for his graduated students and many outstanding engineers today are grateful to "Uncle John" for his assistance in getting a good start. *The Colorado Engineer*, published by the student engineering body, nominated him for the "Hall of Fame." In May, 1936, the engineering faculty held a banquet in his honor and used the occasion to present him with a gold watch. When he retired he was presented with a bronze plaque on which was cast the actual signature of every member of the faculty of the university from the president to the youngest instructor.

For a period of twenty years he served as weather observer for the City of Boulder, but probably the extra-curricular activity which gave him the greatest pleasure was his position as a deputy state oil inspector. During this period every dollar he received from the oil inspector's salary was used to help needy and worthy boys through college by employing them to do extra testing work in the oil laboratory.

Professor Hunter was a member of the Colorado State Board of Examiners for Engineers and Surveyors from 1921 until his death. He rewrote the first Colorado registration law and personally steered the revised law through the Colorado legislature. Because of the intense study which he gave to this work, this new Colorado law is almost a verbatim duplicate of the present "Model Registration Law" of the American Society of Civil Engineers, although it appeared several years in advance of the "Model Law."

Professor Hunter helped develop and helped finance the first mechanically operated vertical automobile storage elevator. The rights to this elevator were purchased by Westinghouse and one operates today in the heart of downtown Chicago. He was also interested in the development of a road "file" and a rotary type engine.

In 1919 romance entered the life of "Uncle John" when he married a member of the faculty, Miss Alice Downing. His marital happiness ran strong but ended abruptly when his bride was suddenly stricken and died in January, 1920. The grief attending this tragedy caused "Uncle John" to be absent from the only Colorado Section meeting he missed from the time he personally organized the Section in 1918 until his own health failed nineteen years later.

Professor Hunter became a member of A.S.M.E. in 1914 and he was one of the first chairmen of the Colorado Section. From 1932 through 1935, Professor Hunter served the Society as manager and during the next two years he was a vice-president. He was elected to the Fellow grade in 1936. From the time he joined the Society until his death he served its interests with an ardor analogous to religious zeal.

Following the death of his wife, a sister, Miss Anna Hunter, presided over his home. The courteous and thoughtful consideration with which he unfailingly treated this sister prompted many appreciative comments. At his death, which occurred on December 17, 1939, Anna Hunter went to live with the other remaining sister, Mrs. A. Woodward Smith of Blairsville, Pa.

Professor Hunter was an active Mason, and a member of Acacia, Tau Beta Pi, and Alpha Chi Sigma. From 1905 until his retirement he was a member of the Society for the Promotion of Engineering Education.

His physical stamina astounded physicians when he recovered from a condition where he seemed completely paralyzed, with death but a matter of hours. His recovery was so s .fficient that he again attended A.S.M.E. meetings, but within the year he succumbed to a combination of uremic poisoning and heart trouble.

On December 19, 1939, he was laid to rest beside his bride of a few months, in Fairmont Cemetery in Denver.—[Memorial prepared by FRANK H. PROUTY, Denver, Colo., Mem. A.S.M.E.]

MELVILLE WILLIAM KANTROW (1880–1937)

Melville William Kantrow, mechanical engineer in charge of inspection for the American Safety Razor Corporation, Brooklyn, N.Y., died on October 15, 1937.

Mr. Kantrow, who simplified his name from Kantrovitz in 1923, was born in Virginia City, Nev., on December 8, 1880, the son of Charles Marks and Henrietta (Mayer) Kantrovitz. His early education was obtained in public schools in New York, N.Y., and at Cooper Union in that city, from whose Art Department he was graduated in 1898.

Following his graduation, Mr. Kantrow worked at various jobs such as assistant draftsman in both mechanical and architectural drafting rooms, and mechanic's helper in machine shops. Then, from 1903 to 1908, he was with the Yale & Towne Manufacturing Co., in Stamford, Conn., first as apprentice and later as assistant in their toolroom, in charge of die work in connection with Keller automatic die sinking machines. From 1909 to 1915, he was employed by Joseph Mayer & Bros., Seattle, Wash., in charge of the manufacture and installation of tower and street clocks and electric time-clock systems. From 1915 to 1919, he worked for the Remington Arms & Ammunition Co., Bridgeport, Conn., first as a foreman in the die room, later being made general foreman in charge of the sub-assembly of the Browning machine gun. He also installed and put into operation a battery of Keller automatic die-cutting machines, and served as assistant in the Drop Forge Department. He designed many jigs, fixtures, and machines to speed up production during the World War.

In 1919, Mr. Kantrow went with the Keller Mechanical Engraving Company, Brooklyn, N.Y., as superintendent of their Automatic Die-Sinking Machine Department, and also directed the setting up and putting into production of these machines for purchasers.

Mr. Kantrow had been employed by the American Safety Razor Corporation since 1926. At first he was engaged in checking production control in the Frame Department. Later he organized an inspection system for the entire plant, also organized and started production in their Double-Edged Blade Department, was in charge of the Pile Wire and Plating Departments, and acted as general "trouble-shooter" in locating and eliminating "choke points" throughout the entire plant.

In 1921, Mr. Kantrow joined the A.S.M.E. as an associate-member and he was automatically transferred to the member grade in 1935. He married Rose Klipper, of New York, in 1928, and is survived by her and by a son, Harry E., of New York, and twins, Lillian and Leon, of Seattle, Wash., as well as by his mother.

MOSES BATES KAVEN (1864–1937)

Moses Bates Kaven, vice-president and consulting engineer of the United Shoe Machinery Corporation, Boston, Mass., died on July 1, 1937.

Mr. Kaven was born on September 28, 1864, at Plymouth, Mass., the son of James M. and Harriet (Barnfield) Kaven. His early education was obtained in the public schools of East Bridgewater; his professional schooling at the Worcester Polytechnic Institute, Worcester, Mass., from which he was graduated in 1885 with the degree of B.S. in mechanical engineering. He was awarded the D. Eng. degree by his alma mater in 1928.

In February, 1886, Mr. Kaven was employed at the Atlantic Works, East Boston, as draftsman on marine engines. In November of that same year, he transferred to the Simonds Rolling Machine Company, Fitchburg, Mass., where he was engaged in drafting work for dies and special machinery for rolled forgings. In October, 1887, he was sent to England and was there employed as works manager of the Simonds Steel & Iron Forging Co., Ltd., of London and Birmingham, until June of 1890.

Mr. Kaven returned to this country in 1890, and became assistant mechanical engineer on marine engines and general machinery with the Lockwood Manufacturing Company, East Boston, Mass. He left there in 1892, and until 1898 acted as assistant to the manager of the Portland Company, Portland, Maine, building marine engines and general machinery and boilers.

In 1898, Mr. Kaven became associated with predecessors of the United Shoe Machinery Corporation, serving successively as superintendent, general superintendent, vice-president in charge of manufacturing, and vice-president and consulting engineer; also as director in sixteen affiliated and subsidiary companies. Mr. Kaven continued in this work until his death.

He became a member of the A.S.M.E. in 1891. He was also a member of the University Club and the Engineers Club, both of Boston; of the Worcester Club of Worcester, Mass., in which city he had resided since 1925; and of the Tedesco Country Club, of Swampscott, Mass. He was a trustee of the Worcester Polytechnic Institute. He was a Republican in politics and a Unitarian in religion.

In 1890, Mr. Kaven married Helen M. Kidder, of West Boylston, Mass., who died on November 30, 1935.

ROBERT RUSSELL KEITH (1879–1937)

Robert Russell Keith, works manager of the Tractor Works of the J. I. Case Co., Racine, Wis., died suddenly on June 12, 1937, while attending the 35th reunion of his class at Iowa State College.

Mr. Keith was born on February 13, 1879, at West Liberty, Iowa, the son of Albert F. and Rachel E. Keith. He obtained his preparatory education in the public high school of West Des Moines, Iowa, where he was later instructor in manual training for a year, and his professional education at the Iowa State College, where he was graduated with a bachelor degree in mechanical engineering in 1902. He then worked as an apprentice machinist in the roundhouse of the Chicago Great Western R.R. Co., South Des Moines, from July to October, 1902. This was followed by service as draftsman in Des Moines with the Eagle Iron Works; one year in the foundry of the Keith Furnace Company, West Liberty; and two years, 1903–1905, with the Louisiana Purchase Exposition at St. Louis. He had charge of the foundation work for all power units for the exposition, some 22,000 hp; was assistant to the superintendent of maintenance and operation; and then directed dismantling and shipping.

Next, Mr. Keith spent five years with the Sight Feed Oil Pump Company, Milwaukee, whose name was later changed to Richardson-Phoenix Company. He acted as shop superintendent and designed the entire line of product. This was followed by six months as assistant superintendent at the A. O. Smith Co., Milwaukee, and eighteen months as general manager, Sterling Machine Company, Norwich, Conn.

From 1912 to 1917, Mr. Keith served as superintendent of the Sheffield Car Company, Three Rivers, Mich., a plant of Fairbanks, Morse & Co.; 1917 to 1919, plant manager of the Holt Caterpillar Company, Peoria, Ill.; 1919 to 1928, as superintendent of the Tractor Works of the Moline Plow Company, Rock Island, Ill., for a short period, and then with International Harvester Company, first as superintendent of Tractor Works at Chicago, and later chief engineer of the Motor Trucks and Bus Division for that company. He took out several automotive patents which he assigned to the company. In January, 1928, he became works manager of the Tractor Works for J. I. Case Co., Racine, Wis., where he was employed at the time of his death.

Mr. Keith joined the A.S.M.E. as a junior in 1904, was promoted to associate in 1911, and to member in 1914. He was also a member of the Society of Automotive Engineers, and at the time of his death was vice-president of that society, representing the Production Engineering Activity. He had also served on the society's National Meetings Committee and the Production, Truck, and Engine Divisions of the Standards Committee.

Mr. Keith married Helen Marks, of Davenport, Iowa, in 1920 and is survived by her and by four children: Dorothy, Herbert, Gordon, and Mary.

JOHN ALFRED ALEXANDER LINDSTROM (1866–1937)

John A. A. Lindstrom, research engineer, National Lead Company, Brooklyn, N.Y., died at the Post Graduate Hospital, New York, N.Y., on September 28, 1937, of uremic poisoning.

Mr. Lindstrom was born on August 20, 1866, in Abo, Finland, the son of Alfred Emanuel and Sophia Gustava (Lindquist) Lindstrom. He obtained both his elementary and professional education in Finland, where he was graduated from the Institute of Technology of Abo in 1884. His first professional employment was as assistant engineer in the office of the city engineer and architect of Abo, from 1884 to 1893. He then emigrated to the United States, and was employed from 1895 to 1899 on the design and construction of new works for Howard & Bullough, American Machine Company, Pawtucket, R.I. In 1903–1904, he worked on the design of the Kingsbridge Power Station, New York, N.Y., and then was employed until 1906 by the Atlas Portland Cement Company at Northampton, Pa., on the design and construction of their plants Nos. 4, 5, 6, and 7. In 1908–1909, he was superintendent of erection and inspector under W. T. Donnelly, chief engineer, for an 8000-ton floating drydock, Erie Basin, Brooklyn.

From 1909 until his resignation in 1929 Mr. Lindstrom was employed by the General Chemical Company, New York, as engineer, estimator, and designer of chemical plants. These were situated in Bay Point, Calif.; Calumet and East St. Louis, Ill.; Newell, Pa.; Pulaski, Va.; Marcus Hook, Pa.; and elsewhere. This work included also wharves and tramways for the Marcus Hook and the Hudson River plants.

In 1934–1936, he was chief engineer, U.S.A., at Fort Hamilton; and in 1937, began his service with the National Lead Company, Brooklyn, and was there employed up to his death.

Mr. Lindstrom joined the A.S.M.E. as a member in 1911. He was also for thirty years a member of the Bergen Beach Yacht Club. He became a naturalized citizen of the United States in 1900, and supplemented his early education in Finland by taking correspondence courses in this country.

He is survived by his widow, Fanny (Spencer) Lindstrom, whom he married in 1920.

ALAN NELSON LUKENS (1867–1937)

Alan Nelson Lukens, chief engineer for the Railway Steel-Spring Division of the American Locomotive Company, New York, N.Y., died at his home in Elizabeth, N.J., on October 20, 1937.

Mr. Lukens was born on March 29, 1867, at McKeesport, Pa. He prepared for college at the Pingry School, and then entered the Stevens Institute of Technology, Hoboken, N.J., where he was a student in mechanical engineering for two years. He left in 1886 to work with Cyrus Currier and Sons, Newark, N.J., as a special apprentice. After two years of this training, he was employed as superintendent by the Conshohocken (Pa.) Tube Company, in charge of their wrought iron pipe mill.

In 1892, Mr. Lukens left this company and took a position as designing engineer for the Artificial Gas Producer Company, Pittsburgh, Pa. He remained there until 1896, when he was engaged as superintendent by the Charles Scott Spring Company, Philadelphia, Pa. Here he had entire charge of the factory, and supervised the erection of new buildings and the reinstallation of all machinery after a destructive fire. In 1902 this company became one of the properties of the newly incorporated Railway Steel Spring Company, and Mr. Lukens was given entire charge of all engineering of five plants, later reduced to three and greatly enlarged. He was responsible for much research and development work on modern steel springs, and numerous inventions and patents on springs, miscellaneous car parts, and special machinery used in their manufacture. After the company became the Railway Steel-Spring Division of the American Locomotive Company in 1926 Mr. Lukens continued active in its affairs up to the time of the short illness which ended his life.

Mr. Lukens became a member of the A.S.M.E. in 1931, and was greatly interested in its work. He was a member of the Special Research Committee on Mechanical Springs from its organization in 1924 up to his death. He also served on the Subcommittees of Heavy Helical Springs and Elliptical Springs. He was a member of the American Society for Testing Materials, and served as Clerk of Sessions for the Westminster Presbyterian Church of Elizabeth.

Surviving are two brothers, the Rev. Victor H. Lukens, rector emeritus of the First Presbyterian and Trinity Church of South Orange, and the Rev. Frank Lukens, rector of the Burlington, N.J., Presbyterian Church; and two daughters, Mrs. Samuel R. MacPhee, of Williamsburg, Pa., and Miss Dorothy Lukens, of Elizabeth.

WILLIS McKEE (1873–1937)

Willis McKee, consulting engineer and contractor, of Cleveland, Ohio, died of pneumonia on December 4, 1937. Mr. McKee was born at State College, Pa., on June 24, 1873, the son of Professor James Y. McKee, then vice-president of The Pennsylvania State College, and Margaret G. McKee.

Mr. McKee spent his entire childhood on the campus of The Pennsylvania State College, and obtained his preliminary education in the A and B preparatory departments there. In 1888 he entered the college in the course in civil engineering, and was graduated with honors with a B.S. degree in 1892. In 1902, he received the degree of M.E. from the college. He was appointed vice-president of the Alumni Association of the college in 1935 and continued in that office until his death. He was also a member of several committees of the association.

After his graduation in 1892, he entered the employ of the Union Switch & Signal Co. and was engaged in erecting block signals along the lines of the N.Y. Central & Hudson River R.R. From 1895 to 1897, he taught in the high school at Mt. Carmel, Pa., and in 1897, he went to work with the Carnegie Steel Company, at Duquesne, Pa., as draftsman. He transferred to the Engineering Department of the National Steel Company, Youngstown, Ohio, in 1899, and after a few months was put in charge of the engineering of their Mill Department. In the early part of 1901, when the National Steel Company became the Ohio Works of the Carnegie Steel Company, he was made chief engineer there. He resigned this position to take the same title with the Republic Iron & Steel Co., in 1902, and in 1904 left that company to become general superintendent of the Elyria Iron & Steel

Co. He remained with this company and its successor, Steel & Tubes, Inc., for about thirteen years, serving as treasurer during the last year.

In 1918 Mr. McKee joined the organization of Arthur G. McKee & Co., which had previously been established by his brother, Arthur G. McKee. For several years he served this company as general superintendent of construction and later as manager of the Mill Department. In 1923 he opened offices as a consulting engineer in Cleveland and was engaged in this business and in marketing rolling mill equipment, on which he had about twenty patents, until the time of his death.

In 1900, Mr. McKee married Sara Pascoe of Carnegie, Pa., and they had two daughters, Margaret R. (McKee) McFarlane, and Helen P. (McKee) Hunzicker, who survive him. He is also survived by two brothers, George C., of Greenville, Mich., and Arthur G., and one sister, Mary (Mrs. H. E. Stitt), both of Cleveland.

Mr. McKee became a member of the A.S.M.E. in 1920. He was also a member of the Cleveland Engineering Society. In the A.S.M.E., he served on the Executive Committee of the Iron and Steel Division as associate in 1933 and 1934, and as member from then until his death.

ALBERT CLEMENT MIDDLETON (1870–1939)

Albert Clement Middleton, son of Frank Barclay and Sally (Albertson) Middleton, was born in Camden, N.J., on November 4, 1870. After attending Friends, a private school in Camden, he entered the Friends' Central High School, Philadelphia, Pa. When he had completed his studies there, he served an apprenticeship under his uncle, Howard W. Middleton, of the firm of C. W. and H. W. Middleton, of Philadelphia, learning the iron and steel trade, and continued in that work until his uncle's death, in 1893, terminated the business.

During the next two years Mr. Middleton engaged in the iron and steel business with H. McCalla, of Philadelphia, with whom his brother, E. M. Middleton, and Walter Ivins were also associated, and from 1895 to 1897 he was connected with the Cole Machine Company, Camden, manufacturers of engines for steam launches and small boats.

In 1897 Mr. Middleton joined Eldridge R. Johnson, Camden, who had a machine shop there and contracted for the making of all motors for the Berliner Gramophone Company, of Philadelphia. Mr. Middleton served as secretary of the business until 1901, when it was incorporated as the Victor Talking Machine Company, and from then until he retired in 1913 he was this company's secretary and assistant treasurer.

Mr. Middleton took an active part in civic and political affairs in the State of New Jersey. He was elected treasurer of the state on January 31, 1928, and served until April 1, 1934. He had been chairman of the South Jersey Port Commission since its organization in April, 1926. This commission constructed port facilities at Camden, where it operates the Camden Marine Terminals, and has aided greatly in developing transportation to serve the industrial and commercial interests of South Jersey.

Mr. Middleton had also served as a director of the West Jersey & Seashore R.R. Co., and of the First Camden National Bank & Trust Co., the Camden Safe Deposit & Trust Co., and the Camden Fire Insurance Association. He became an associate of the A.S.M.E. in 1911, and was a member of The Franklin Institute, the Camden County Historical Society, and several clubs in New York and Philadelphia. Gunning, yachting, and fishing were his chief recreations.

Mr. Middleton's death occurred on March 4, 1939. He is survived by Mrs. Middleton, the former Rena E. Lord, of Haddonfield, N.J., whom he married in 1898, and by a daughter, Rena.

ALBERT ELIPHALET MITCHELL (1855–1937)

Albert Eliphalet Mitchell, president and treasurer of the Wyckoff Pipe & Creosoting Co., Inc., New York, N.Y., died on December 26, 1937. He was born in Madison, Maine, on February 3, 1855, son of Thomas Gilmore and Laura Ann (Packard) Mitchell.

Mr. Mitchell's preliminary education was obtained in the common schools, and he later attended the University of Maine, which in his student days was known as the Maine State College of Agriculture and the Mechanic Arts. He was graduated as a mechanical engineer in 1875, of which class he is believed to have been the last surviving member.

Mr. Mitchell served as apprentice machinist with the Baldwin Locomotive Works in 1876–1877 and then entered the employ of the Pennsylvania Railroad at Altoona, Pa., where he worked successively in the machine shop, the Test Department, and the Signal Department. He then spent a year, 1881–1882, in the Yale & Towne Manufacturing Co., Stamford, Conn., as a designer of hoisting machinery, followed by two years as chief draftsman with the old New York & New England R.R., now a part of the New York, New Haven & Hartford R.R. He next spent about two years in Cleveland, Ohio, where he was employed as mechanical engineer and plant superintendent by the French Furnace Company and the Arctic Ice Machine Manufacturing Company. In 1886 and 1887, he was employed by the New York, Lake Erie & Western R.R. Co. (now the Erie Railroad) on special work in the Motive Power Department; from 1887 to 1889, he was engineer of signals; in 1889 and 1890, engineer of tests; from 1890 to 1892, mechanical engineer; and from 1890 to 1902, superintendent of motive power.

In 1901–1902, he was assistant superintendent of motive power for the Chicago, Milwaukee & St. Paul R.R., and in 1902–1904, superintendent of motive power for the Northern Pacific Railroad. In 1904–1906, he held a similar position with the Lehigh Valley Railroad, and in 1906–1908, was employed by the N.Y., N.H. & H. Railroad, on appraisal of rolling stock and as manager of purchases and supplies, fuel agent, etc. In 1908, Mr. Mitchell became vice-president of the Wyckoff Pipe & Creosoting Co., later becoming its president and treasurer, and continuing in this position to the time of his death. He held several patents, chiefly in the railway field.

Mr. Mitchell became a member of the A.S.M.E. in 1891. He was also a member of the N.Y. Railroad Club and served as its president from 1896 to 1898. He belonged to the Cleveland Engineering Society, the Mayflower Society, and the Phi Gamma Delta fraternity.

He was twice married. His first wife was Nellie Vernon Knapp, whom he married in Stamford, Conn., in 1884; his second wife was Mrs. Eliza Anna Wyckoff, nee Corel, whom he married in 1908, and who died in 1933. He had one daughter, Hazel Vernon, who also predeceased him.

Mr. Mitchell was a member of the Jury of Awards of the Paris, France, Exposition of 1892. He was for many years a member of both the Master Car Builders' and the Master Mechanics' Associations, and during that time, wrote various reports for these associations.

GEORGE LUTON MORTON (1858–1937)

George Luton Morton, former primary examiner in the U.S. Patent Office, who retired on June 30, 1932, after forty-six years of service in the Patent Office, died on May 13, 1937, in Washington, D.C., of pneumonia. He was born on August 19, 1858, at Parkman, Ohio, the son of Perry and Laura (Chapman) Morton.

Mr. Morton took a six-years' course in mechanical engineering in the Ohio State University, graduating in 1884, during which time he worked at intervals in various shop processes outside the university. He later took a three-years' course in law at the National Law School, Washington, D.C., and was admitted to the bar in the spring of 1889. He was also admitted to practice before the Supreme Court of the United States.

After his graduation in 1884, he was variously engaged: for one year as teacher of mechanical drawing in the School of Design, Cleveland, Ohio; as draftsman for Professor Robinson at Columbus, Ohio; and as a student of patent law in the office of Ex-Commissioner Gen. M. D. Leggett at Cleveland; also on the mathematical work connected with an article, "Cushioning in Engines," published in Van Nostrand's *Engineering Magazine*, June, 1885. Following these activities, Mr. Morton worked for nine months as machinist and draftsman for the Cleveland Rubber Company, and then went into the office of the superintendent of motive power, New York, Lake Erie & Western Railway Company, as draftsman. He remained here until 1886, when as the result of a successful competitive examination he was appointed an assistant examiner in the U.S. Patent Office, and assigned to Division 13.

Mr. Morton rose to be chief clerk in the Patent Office, in 1895, and three years later was appointed primary examiner of Division 36, which was organized under his supervision. He held this position until his retirement in 1932. He became a member of the A.S.M.E. in 1890; he was also a member of the Masonic order and of the University Club in Washington.

He married, in 1905, Alice M. B. Simmons, of Washington, D.C., who survives him.

ANDREW HENRY NEUREUTHER (1877–1937)

Andrew Henry Neureuther, consulting engineer and patent attorney for the Westclox Division of the General Time Instruments Corporation, of La Salle and Peru, Ill., was killed in an automobile accident on October 16, 1937, near Princeton, Ill.

Mr. Neureuther was born on April 3, 1877, at Peru, the son of Charles F. and Louise (Oesterle) Neureuther. He attended the Peru schools and entered the University of Illinois in the Mechanical Engi-

neering Department with the Class of 1898. After being granted his B.S. degree in mechanical engineering he spent a year in postgraduate work at the University, securing his M.E. in 1899. He then joined the staff of the Western Clock Company, La Salle, a small local plant, as engineer. Mr. Neureuther grew up with the company, soon becoming its chief engineer, a position he held until 1932, when he was made consulting engineer and patent attorney. As chief engineer, he supervised every addition to the plant from 1899 on, one of his first jobs being to change the illuminating system over from gas to electricity. The modernization of the heating and power plants, the establishment of physical and chemical testing departments and an experimental machine shop, the conduct of research, and the design and manufacture of special machinery all came under his supervision. He held some twenty patents in the United States and Great Britain relating to clocks and clock parts, and particularly to automatic casting machines and other special machinery used in the manufacture of clocks.

In addition to his engineering course, Mr. Neureuther took up the study of law in his spare time, specializing in patent law, and secured his LL.B. degree from the Chicago Correspondence School of Law in 1903 and shortly thereafter was admitted to the Illinois Bar Association. In 1930 the Western Clock Company was acquired by the General Time Instruments Corporation, of which it became the Westclox Division, and since 1932 Mr. Neureuther had devoted practically all of his time to the patent work of the corporation. He attained a wide reputation in patent work and had served as an expert witness in important cases.

Mr. Neureuther was a contributor to technical publications including the *Street Railway Review* and *Machinery*. He was serving as president of the National Sheet Metal Company and of the Citizens' Hotel Company, both of Peru, at the time of his death and had served as director of The Illinois Zinc Company and The Central Life Insurance Company of Illinois, Chicago, and of two banks in Peru.

Mr. Neureuther became a junior in the A.S.M.E. in 1899, and was promoted to the member grade in 1928. He was a member of Tau Beta Pi, honorary engineering fraternity, and of the Masonic order and was active in many organizations for community betterment. He had served as a trustee of the Peru Congregational Church, president of the public library board, vice-president of the Business Men's Association, and member of the school board and hospital association, and was actively interested in Boy Scout work. He was also secretary of the executive board of the Civic Federation of La Salle, Peru, and vicinity, and president and director of the Ottawa (Ill.) Chautauqua Association.

In 1902 he married Nettie Jane Robinson, of La Salle, who died in 1922. Three children, Anita Nettie Connellee, Andrew Wesley Neureuther, and Mabel Elaine Small, survive him. In 1926 Mr. Neureuther married Ada M. Baysoar, who also survives him.

CARL VICTOR NORDBERG (1872–1937)

Carl Victor Nordberg, of the Nordberg-Rowe Engineering Company, Butte, Mont., died on June 3, 1937, of angina pectoris.

Mr. Nordberg was born in Björneborg, Finland, on July 10, 1872, the son of Carl Victor and Dores (Heinze) Nordberg. His education and early engineering experience were acquired in Finland, where he was graduated with an M.E. degree from the Polytechnic Institute of Finland in 1900. Prior to this, he was employed from June to September, 1896, with Abo J.M.A.B., manufacturers of steam engines; from September, 1896, to June, 1897, with Nobel Bros., St. Petersburg, builders of mining machinery and steam engines; from June to September, 1897, and in 1898, with Björneborg Mek. Verkstad, Finland, builders of steamships and marine machinery; from June, 1899, to August, 1900, with A. G. Electricitäts Werke Vorm. Kummer & Co., Dresden, Germany, as assistant to the chief engineer, building an electric railway and power plant for the city of Helsingfors, Finland.

Following his graduation from the Polytechnic Institute Mr. Nordberg came to the United States and entered the employ of the Nordberg Manufacturing Company, Milwaukee, Wis., which had been founded by his older brother, Bruno V. Nordberg (Mem. A.S.M.E.; for obituary see Trans. A.S.M.E., vol. 46, 1924, page 1318). For about five years he worked on designs for air compressors, blowing engines, hoisting, pumping and stationary steam engines and stamps.

From September, 1905, to August, 1916, Mr. Nordberg served as representative of the Nordberg Manufacturing Company in the western states, selling machinery and supervising the installation of power plants. In August, 1916, he formed the corporation known as C. V. Nordberg Machinery Company, at Butte, Mont. On November 1, 1919, he assumed charge of the Missoula Iron Works, which he managed in addition to the C. V. Nordberg Machinery Company until October, 1924. In November, 1926, he became associated with the Nordberg-Rowe Engineering Company as consultant in research and engineering. He terminated this connection in 1932 to devote his time to designing and building portable compressors, which line he followed up to the time of his death. He supervised the installation of compressor valve systems for a number of mining companies, and a central compressor plant for the Anaconda Copper Mining Company, Butte, Mont., one of the largest of such plants in the world. He took out several patents, including one on cooling towers, and one on clutches.

Mr. Nordberg became a member of the A.S.M.E. in 1908. He was a member of the Navy Consulting Board of the United States, appointed by Secretary Josephus Daniels, in September, 1916. He became a naturalized citizen of the United States in 1912.

In 1902, Mr. Nordberg married Ida Viola Stenstrom in New York, N.Y. She died on February 27, 1924. He is survived by a daughter, Greta (Nordberg) Quayle, and a son, Carl Victor Nordberg, Jr., both of Butte, Montana; also by two grandchildren, Dolores Ann Quayle and Carl Victor Nordberg.

JULIAN DAY PAGE (1873–1936)

Julian Day Page was born at La Salle, Ill., on April 6, 1873, son of Thomas Mason and Kata (Brown) Page. He was graduated from Purdue University in 1894 with a bachelor's degree in mechanical engineering and took his master's degree three years later. During that period he worked on crane design for the Whiting Foundry Equipment Company, Harvey, Ill. From 1897 to 1901 he worked in Cleveland, Ohio, first for the Brown Hoisting Machinery Company, then for the McMyler Manufacturing Company, on crane design. He went to Youngstown, Ohio, in 1901, and for about three years was chief engineer for the Youngstown Engineering Company, also in connection with crane manufacture.

In 1904 he turned to plate work as chief engineer of the Enterprise Boiler Company, of Youngstown. He continued in this field for some years, working for the Wm. B. Pollock Co., Youngstown, from 1905 to 1907 and again, as assistant engineer, in 1910–1911; at the Ohio Works of the Carnegie-Illinois Steel Corporation, Youngstown, in a similar capacity, from 1907 to 1910; and for the Struthers Furnace Company, at Struthers, Ohio, as chief engineer, from 1911 to 1915. He received a safety medal in connection with his work in this position.

Subsequently Mr. Page spent about a year each with the Wm. Tod Co., Youngstown, and Mark Manufacturing Company, Chicago, Ill., and then went to New York, where he was chief draftsman with Perin & Marshall for several years. From May, 1918, until March, 1920, and again from July, 1923, to June, 1932, he was connected with the Wilputte Coke Oven Corporation, New York, as chief draftsman during the most of the time. He was with the International Coal Products Corporation in Newark, N.J., in 1920–1922.

Since 1934 he had been designing engineer for the Lummus Company, New York. He died in Plainfield, N.J., on February 3, 1936, after an illness of almost a year.

Mr. Page became a member of the A.S.M.E. in 1918. He was a Knight Templar and 32nd degree Mason. He was much interested in horticulture and in the promotion of welfare for crippled children.

Surviving Mr. Page are his widow, Helen Grinnell (Sill) Page, whom he married in 1903, and two children, Julian Day Page, Jr., and Helen Jane Page, who reside with their mother in Westfield, N.J.

EDMUND J. MASON PARRY (1876–1937)

Edmund J. Mason Parry, for more than thirty years associated with the Hartford Steam Boiler Inspection & Insurance Co., died suddenly at his desk in the home office of that company in Hartford, Conn., on October 4, 1937.

Mr. Parry was born on October 10, 1876, at Menai Bridge, Isle of Anglesey, North Wales. He was educated in Menai Bridge and Beaumarais schools and then served apprenticeships with De Winton, Carnarvon, Wales, and with Harland and Wolff, shipbuilders and engineers, Belfast, Ireland. At the completion of this course of training in 1896, Mr. Parry went to sea as assistant engineer in the Dominion Line Steamship Company, Liverpool, England, and in December, 1900, he was granted the certificate of the British Board of Trade as first-class marine chief engineer. He continued at sea, after transferring to the White Star Line in 1900, until April, 1906, with the rank of Engineer Officer, assistant to the chief engineer.

In June, 1906, having emigrated to the United States, Mr. Parry joined the Hartford Steam Boiler Inspection & Insurance Co. as inspector of steam boilers and flywheels, in its Boston office. He occupied this position until March, 1913, when he was transferred to Hartford as directing inspector for the company, in charge of the inspection of details relative to the design, construction, and installa-

tion of boilers and other pressure vessels, with authority over the work of other inspectors.

Following the death of Frank S. Allen in 1918, Mr. Parry succeeded to the position of chief inspector. For the next five years he served as head of the home department's inspection staff and in 1923 was transferred to the New York department as chief inspector. In the spring of 1933 he was granted leave of absence for rest and recuperation from a long illness and spent the next several months in his native England. On his return Mr. Parry went to Hartford as a member of the engineering staff of the boiler division and served in this capacity until the time of his death.

Mr. Parry became a member of the A.S.M.E. in 1918. He belonged to the Masonic fraternity and was a Shriner and a member of the Order of de Molay. For many years he was associated with the Hartford Hospital as a member of the board of directors and at the time of his death was its secretary. He was also a member of the Municipal Incinerator Commission, and of the Trinity Episcopal Church of Hartford. His clubs included the St. David Society of the State of New York, and the Professional Engineers Club of Connecticut.

He is survived by his wife, Elizabeth (Olson) Parry; three sisters in England; and a brother, Osmond Parry, in South America.

JOHANN FRIEDRICH MAX PATITZ (1866–1937)

Johann Friedrich Max Patitz—generally known as Max Patitz—chief consulting engineer for the Allis-Chalmers Manufacturing Company, Milwaukee, Wis., died suddenly of a heart attack on January 3, 1937.

Mr. Patitz was born on May 21, 1866, in Muegeln, near Leipzig, in Saxony. The following account of his life is based largely upon an obituary in *Milwaukee Engineering*, Vol. XVII, No. 4, of January, 1937.

He was educated in the Citizens' School and Royal High School or Gymnasium, of Dresden. With his parents, he emigrated to the United States, and found his first employment in Pittsburgh, Pa., where he spent four years working in various factories and machine shops. Then, in June, 1885, he entered the employ of the Edward P. Allis Company at the Reliance Works in Milwaukee, where he held a number of successive minor positions during the first years. His ability, however, soon found recognition, both by Mr. Allis and the late Edwin Reynolds, and he was transferred to the engineering department. He became one of the company's designing engineers; and in 1901, when the Edward P. Allis Company became part of the Allis-Chalmers Company, he was put in charge of the building of steam engines and compressors. As early as 1899, Mr. Patitz saw the possibilities of the steam turbine, and in 1902 he was sent abroad to investigate the subject, and on his return did much to further the building of steam turbines by the company. He later made other trips to Europe for the company, investigating the various designs of gas engines, diesel engines, compressors, tillers, and tractors, and was intimately connected with the early development of Allis-Chalmers tractors and farm machinery.

Mr. Patitz was granted many patents. His studies of the parallel operation of alternating-current generators began as early as 1900. He became an outstanding authority on critical speeds and vibrations in high-speed machinery, and on the intricate mathematical calculations of modern machine design.

Mr. Patitz became a junior member of the A.S.M.E. in 1891 and a member in 1900. He was appointed a member of the Power Test Codes Committee No. 5 on Reciprocating Steam Engines in January, 1918; and of the P.T.C. Committee No. 20, on Speed Responsive Governors, in April, 1922, and was still serving on these committees at the time of his death. He was also a member of the Subcommittee on Steam of the Research Committee from the time of its appointment in 1911 until the completion of its work in 1915. In addition, Mr. Patitz was a member of the Society of Automotive Engineers, Verein deutscher Ingenieure, Engineers' Society of Milwaukee, American Society of Agricultural Engineers, American Association for the Advancement of Science, and Deutsche Landwirtschafts Gesellschaft.

FRANCIS GLADHEIM PEASE (1881–1938)

Francis Gladheim Pease was born at Cambridge, Mass., on January 14, 1881, and received his early education at Highland Park, Ill. He studied science and engineering at Armour Institute of Technology, Chicago, and received his B.S. degree in 1901. His alma mater conferred the degree of M.S. in 1924 and Sc.D. in 1927. While attending Armour, Pease worked evenings and weekends in the optical shop of Petitdidier, where he mastered many practical details of instrument making.

After graduating from Armour, Pease was recommended by Petitdidier to Professor G. W. Ritchie of the Yerkes Observatory. Here he first took part in the routine work of grinding lenses and mirrors and later began work in instrument design under Professor Ritchie and also took part in the astronomical work as an observer under Dr. George Ellery Hale. This was a splendid apprenticeship for a man who combined great mechanical talent with good training in engineering theory. To these Pease also brought imagination and great enthusiasm.

When the work at Mt. Wilson Observatory was inaugurated in 1904 under a grant from Carnegie Institution, Pease and others accompanied Dr. Hale to Pasadena, Calif. Much of the development of this fine observatory must be credited to Dr. Pease. He designed in large part the Snow telescope, the 60- and the 150-ft tower sun telescopes, the 60- and 100-in. reflecting telescopes, the 50-ft interferometer, besides a great host of auxiliary instruments. He also supervised much of the work of grinding and testing the 60- and 100-in. reflectors. After the erection of the 60-in. telescope, Dr. Pease carried on the regular work of an astronomer. His astronomical observations cover a wide range, including fine photographs of star clusters and faint nebulae which are used for comparison with previous and later observations. He made many observations of the spectra of faint nebulae. His moon photographs are said to be the finest in existence.

In 1919 Dr. Pease assisted Dr. A. A. Michaelson in designing and constructing a giant interferometer and in measuring the diameter of Betelgeuse. Later, Pease made other measurements of the diameters of many of the nearer stars. He also assisted Dr. Michaelson in two determinations of the velocity of light, the last of which was completed by him after Dr. Michaelson's death. In this later experiment he designed and built a pipe line a mile long which was evacuated to one one-thousandth of an atmosphere. In 1929 he repeated the famous Michaelson-Morley experiment on ether drift, using an 85-ft interferometer, and confirmed the previously found negative results.

Following the design of the 100-in. telescope, Pease became greatly interested in the design of still larger telescopes. In 1926 he made a careful study of the problems involved in the design of a 300-in. reflector. He advocated the fork type mounting and proposed the use of pyrex glass for the mirror.

When the work on the 200-in. reflector was inaugurated in 1930 at the California Institute of Technology, Dr. Pease devoted half of his time to assisting in the design. He was engaged in this work at the time of his very sudden illness and death, on February 7, 1938.

Dr. Pease had been a member of the A.S.M.E. since 1915 and served the Society as chairman of the Los Angeles Section and in many other capacities. He is survived by his widow whom, as Miss Caroline T. Furness, he met at Yerkes Observatory and married in 1905. Dr. Pease was a large man, a viking physically, and he radiated health and friendliness. He will be sorely missed.—[Memorial prepared by Wm. Howard Clapp, Pasadena, Calif., Mem. A.S.M.E.]

HARRY ADAM PICKEL (1874–1937)

Harry Adam Pickel, superintendent of generation for the Pennsylvania Power & Light Co., at Hazleton, Pa., died on January 18, 1937, in the Good Samaritan Hospital at Lebanon, Pa., the result of an automobile accident two days previously.

Mr. Pickel was born at Montclair, Pa., on August 11, 1874, the son of Uriah Leonard Pickel and Elizabeth (Van Artsdalen) Pickel. He had no formal education beyond grammar school and home study work. From 1893 to 1896, he served an apprenticeship at woodworking with Samuel Gourley of Philadelphia, from which he entered the employ of M. R. Mucklé, Jr., & Co., electrical and mechanical engineers and contractors. Here he served as electrical mechanic and foreman on several important jobs, the largest being the United States Gas Improvement Building at Broad and Arch Streets, Philadelphia, when he was in charge of all electrical work. In 1899, Mr. Pickel went to the Philadelphia Bourse Building as electrician, and had become assistant chief engineer when he left, in 1902, to serve as superintendent and chief engineer of the Colonial Trust Building, Reading, Pa., a new building, ten stories high, and the first modern office building in that city.

In 1906, Mr. Pickel joined the staff of the Engineer Company of New York, specialists in boiler efficiency and owners of the balanced draft system. After serving for some time in New York as salesman and superintendent of construction, he was sent to Philadelphia as district manager, and while there he designed and built the first device to operate the damper of a steam boiler by the variation of the furnace gases.

From 1908 to 1913, Mr. Pickel was building superintendent and chief engineer of the Central Branch Y.M.C.A. in Philadelphia, one of the largest Y.M.C.A. buildings in the country, and he was also its house manager. He was also consulting engineer for the General

Board of the Y.M.C.A. in Philadelphia and in that capacity designed the plumbing, heating, and electrical work for the Elkins Memorial addition to the Central Branch, and also power plants for other branches in the city.

In 1913, he went into business with two partners as the Quaker City Engineering Company, of Philadelphia. This business was terminated in 1916, because of lack of capital, and Mr. Pickel became superintendent of power for the Hercules Powder Company, Kenvil, N.J. Here he remained until August, 1919, when he took the position of superintendent of the Hauto Steam Electric Station of the Pennsylvania Power & Light Co. He became superintendent of generation for the company on April 1, 1925.

Mr. Pickel joined the A.S.M.E. as an associate-member in 1917, and was automatically transferred to the grade of member in 1935. He was active in the establishment of the Lehigh Valley Section in 1920, and was one of the promoters in the expansion of the territory to include the anthracite area, which occurred in 1928. He was chairman of the Executive Committee of the Anthracite-Lehigh Valley Section in 1935–1936, and vice-chairman in 1928–1929, 1931–1934, and 1936–1937.

In 1901, Mr. Pickel married Bertha May Hubbs, who survived him though injured in the same accident that was the cause of her husband's death. He was also survived by two sons, Harry A., Jr., living in Ringtown, Pa., and Robert, who was a student at Gettysburg College at the time of his father's death.

In addition to his membership in the A.S.M.E., Mr. Pickel had been a member of the Engineers Club of the Lehigh Valley since its organization in 1921, and served on important committees at various times. He was active in the work of the Boy Scouts of America, and of the Rotary Club. He was a Royal Arch Mason and Knight Templar and a member of the First Presbyterian Church of Hazleton, Pa., in which he served as president of the Men's League.

EDWARD RIVETT (1851–1937)

Edward Rivett, of Allerton, Mass., died on December 16, 1937, of thrombosis of the brain, after a nine weeks' illness.

Mr. Rivett was born on January 5, 1851, in L'Assomption, Que., Can., the son of Antoine and Elise (Marsolais) Rivett. He had only a common school education, and went to work in 1865 in a cotton mill, at Manville, R.I. In the following year he also worked in a cotton mill, in Holyoke, Mass. He then put in two years in shoe shops in Worcester and Lynn, Mass.; then two years as night overseer in a textile factory in Baton Rouge, La. In 1871, he was employed by the N.Y. Watch Co. in its factory in Springfield, Mass., and this started him on what he made his lifework. He went to Boston in 1872, and got work with C. A. W. Crosby, watchmaker and jeweler. He invented a number of watchmakers' tools, and in 1884 started manufacturing tools and lathes with Mr. Crosby as silent partner, under the firm name of the Faneuil Watch Tool Company, at Faneuil, Mass. The first "factory" was a wooden extension of his own home. After Mr. Crosby's death, Mr. Rivett bought out his interest and incorporated the business as the Rivett Lathe Manufacturing Company, Brighton, Mass.

In 1912, Mr. Rivett sold out this business on account of failing health. From then on up to his death, he considered himself as "retired," but he continued to experiment and improve watchmaking tools and machinery, often remarking to friends that he was "too busy to take a vacation."

During his early days with Mr. Crosby, he had his first experience in the buying of diamonds, in which he became an expert.

Concerning his work the *American Machinist*, in its issue of December 29, 1937, said, in part:

"Mr. Rivett believed himself to be the originator of precision in bench lathes and small internal grinders. Unusual mechanical skill, an inquiring mind, and initiative were qualities that aided Mr. Rivett in building precision into his machines. His designs were worked out at the bench and his men built early models from sample pieces. In the search for greater precision he visited many shops in this country and abroad to pick up ideas or materials. From Switzerland he obtained gages, in Turkey he bought a lifetime supply of lapping powder. If he wanted special gib stock, he went directly to the mill and showed them what he needed. In his opinion many modern shops have an impersonal attitude toward their products, and it was his delight to find one where no amount of time or trouble was too much to give in the search for perfection."

Mr. Rivett became a member of the A.S.M.E. in 1904. He was a Knight Templar and a Shriner. He was a skilful fisherman, good shot, and excellent woodsman, and was very fond of such recreation. His wife, Alma (Pinceloup) Rivett, whom he married in 1882, died in 1895. A daughter, Ida F. (Rivett) Lockwood, of Newton, Mass., survives him.

MARTIN LUTHER SIBERT (1908–1937)

Martin Luther Sibert, a junior member of the A.S.M.E., died on March 31, 1937. He was born on December 1, 1908, in Gadsden, Ala., the son of Samuel Houston and Emma Lula (Penny) Sibert, and was a nephew of Major-General William L. Sibert, Retired, of the U.S. Army Corps of Engineers.

He prepared for college in the Gadsden High School and was graduated, with a B.S. degree in mechanical engineering, from the Georgia School of Technology in 1931, later studying electro-acoustical engineering through correspondence courses. During part of 1932–1933 he was engaged in business for himself as a merchant and subsequently was employed by the U.S. Geological Survey as an engineering draftsman and computer, assigned, since August 15, 1934, to the Tennessee Valley Authority, in Chattanooga, Tenn.

Mr. Sibert became a member of the Student Branch of the A.S.M.E. at the Georgia School of Technology in 1928, and transferred to junior membership in the Society in 1932. He was commissioned as second lieutenant in the 345th Infantry Reserve in 1930. He was unmarried.

EDMUND RAY STEVENSON (1859–1935)

Edmund Ray Stevenson was born at Burgettstown, Pa., on April 14, 1859, and received his early education at the public school there, which was in session only for a six months' winter term. Nevertheless, at the age of eighteen he passed an examination qualifying him to teach in the public schools of his native county of Washington. Because of his youthful appearance, however, the superintendent of schools thought it best not to make the certificate valid.

Mr. Stevenson therefore entered upon an apprenticeship in the steamboat shop of James Rees in Pittsburgh, upon the completion of which he secured employment with the Yale & Towne Manufacturing Co., Stamford, Conn. Here he studied steam engineering under James McBride (Mem. A.S.M.E.) and Thomas Shaw, who later founded the Shaw Crane Company. He continued his studies under H. P. Morgan, chief engineer of the Norwalk Iron Works Company, South Norwalk, Conn., where he spent 15 years as machinist, toolmaker, toolroom foreman, supervisor of machine repairs, and designer of jigs, tools, and fixtures. He was also one of the early pupils of the International Correspondence Schools, enrolling in the mechanical course in January, 1901. This course enabled him to teach evening classes in mechanical drawing and mathematics.

He left the Norwalk Iron Works Company to work as tool designer under Joseph E. Aue (Mem. A.S.M.E.) for the De La Vergne Machine Company, New York. During a year there he helped to design, among other things, an attachment for use on planers to plane cylindrical valve stems, a cam grinder, a cylinder boring mill, and a large floor milling machine. For the next five years he was in charge of power and transmission at the plant of the Union Hardware Company, Torrington, Conn., and performed all the millright work. He supervised the installation of considerable new equipment and the construction of a new grinding room.

The remainder of Mr. Stevenson's work was in Detroit, Mich. He was employed by The Timken-Detroit Axle Company in 1915 as tool trouble man and four years later was transferred to the Tool Design Department. He taught in the vestibule or shop training school throughout the World War, and improved the company's practice in the welding of tools by substituting a butt-welding machine for the spot-welding machine that was formerly used to join the high-speed steel and Stellite tips to cold-rolled stock, thereby effecting savings in time and current.

He next went to the Kelsey Wheel Company to design tools for the manufacture of Ford front tractor wheels. This led to his connection, in 1924, with the Ford Motor Company, to design and build fixtures for body assembly; he also installed safety attachments on cranes, and improved the tools used in the plant and the fixtures for repairing them. He was appointed an instructor at the Henry Ford Trade School in 1928 and remained there until 1933.

Mr. Stevenson was especially interested in increasing production by the standardization of parts, and the use of conveying systems instead of men and trucks to move material from one part of the plant to another. In addition to the work already mentioned, he invented an attachment for use in connection with universal cutter and tool grinders, and developed a multiple stamp mill for the Stamford Bronze Company, and a line of machinery for the Boas Thread Company which would print labels, stamp and label spools, and wind thread.

He joined the A.S.M.E. in 1921 as an associate-member but resigned in 1927. He was reinstated as an associate-member in 1933. His death occurred on June 29, 1935. Mrs. Ethel R. Stevenson, of Detroit, survives him.

GEORGE GODFREY STEWART (1888–1937)

George Godfrey Stewart, engineer at the Donora Steel Works of the American Steel & Wire Co., Donora, Pa., died on January 14, 1937, of an embolism following an operation for appendicitis.

Mr. Stewart was born at Merchantville, N.J., on December 23, 1888, the son of Wickliff Baldwin and Justina (Godfrey) Stewart. He was graduated from Temple University in 1907, and from Drexel Institute in 1916. He served a special apprenticeship from 1904 to 1907 as a machinist with the Pennsylvania Railroad ferries at Camden, N.J., and two further years, 1908–1910, in the P.R.R. shops at Hoboken, N.J. During the latter period, he secured considerable engineroom experience on P.R.R. ferry- and tugboats in New York harbor, and before and during his course at Drexel Institute he piloted ferryboats of the P.R.R. between Camden and Philadelphia.

In 1916–1918, Mr. Stewart was inspector of tests in the Test Department of the P.R.R., with headquarters at Altoona, Pa. In 1918–1919, he served as assistant superintendent of shop and field machinery at the Gloucester, N.J., and Bristol, Pa., plants of the U.S. Shipping Board, Emergency Fleet Corporation. He began work for the American Steel & Wire Co. in 1921 as machine operator in the shops at Donora, and in 1922 was made foreman of the Engines and Pumps Department. Retrenchments by the company necessitated his transfer to work as engine repairman in May, 1932, but the following year he was placed in charge of the boiler house, with the title of head engineer, and continued in that position until his death. He held patents on a safety valve and on a key ring.

Mr. Stewart joined the A.S.M.E. as an associate-member in 1928, and was automatically transferred to the member grade in 1935. He was a member of the Engineers Club of Philadelphia from 1914 to 1938. He was also a member of the Masonic order and a Shriner.

In 1920, Mr. Stewart married Margaret M. Pipes of Donora, Pa., who survives him.

WILLIAM FRASER STEWART, JR. (1897–1937)

William Fraser Stewart, Jr., chief engineer in connection with fire prevention and safety engineering work with W. H. Markham & Co., St. Louis, Mo., died at the Central Hospital, in that city, on September 9, 1937, of a duodenal ulcer.

Mr. Stewart was born in St. Louis on January 1, 1897, the son of William Fraser and Daisy Beatrice (Lamb) Stewart. His formal education ended with the completion of three years in the Central High School, St. Louis, after which he served an apprenticeship with David Ranken, St. Louis, and with Hispano Suiza, Paris, France.

In July, 1917, he enrolled in the U.S. Naval Reserve Force at St. Louis, as chief machinist's mate, and was sent to France, where he was assigned to aviation, in charge of bomb sight design and machine shops at St. Trojone. On his return to the United States in 1919 he became superintendent of the American Heater Corporation, St. Louis, designers and builders of automatic water heaters. He held this position until 1922, and then served until 1925 with the Western Electric Company as division inspector, in charge of inspection and tests of automatic telephone exchange apparatus. In 1925, Mr. Stewart was appointed engineer for the Ocean Accident & Guarantee Corp., his duties relating to safety engineering, general consulting work, and the inspection of powerhouse equipment. His association with W. H. Markham & Co., began in 1930. In addition to his responsibilities as chief engineer he served the company in connection with building and equipment values, on which he was well informed.

Mr. Stewart joined the A.S.M.E. as an associate-member in 1929, and was automatically transferred to the member grade in 1935. He was also a member of the Safety Council, St. Louis, Army Ordnance Association, and American Legion, and a former member (1924) of the Flying Club of St. Louis, and belonged to the Masonic Lodge in Clayton, Mo. He founded and was chief of the West Overland (Mo.) Fire Department (volunteer) from 1929 to 1934, when it was disbanded. He continued in the Naval Reserve Force for a number of years after the War, finally accepting his discharge in 1925. He was an excellent shot and made a hobby of collecting old firearms.

He married Marion Clare Williams in 1927, and is survived by her and their three children, William Robert, John Fraser, and Beverley Ann.

ARCHIE MILTON STILES (1878–1937)

Archie Milton Stiles, who had been connected with the Water Division of the Department of Public Utilities of the City of St. Louis, Mo., since 1901, died in that city on March 5, 1937. Mr. Stiles was born in St. Louis on June 9, 1878, the son of Andrew and Catherine (Cathbert) Stiles, and secured his preliminary education in the public schools there; his professional education he obtained through the International Correspondence Schools.

From 1892 to 1896 he worked as machinist-apprentice with the Rankin-Fritsch Foundry & Machine Co. of St. Louis and during the next five years he was machinist with several different companies, making dies, castings, and tools. In 1901, he began his long service with the Water Division of the City of St. Louis. He served until 1905 as machinist and from then to 1912 as foreman of machine, blacksmith, tin, and pattern shops. In 1912, he became inspector for steam boiler and pumping machinery, and held this position until 1920, being resident inspector at various plants throughout the United States, during the manufacture of pumps, boilers, compressors, valves, piping, and general supplies and machinery for the City of St. Louis. In 1930, Mr. Stiles was appointed superintendent of construction of mechanical equipment by the City Water Division, and was so employed up to his death.

He joined the A.S.M.E. as a member in 1930, and was also a life member of the Masonic fraternity and of the Low Twelve Club of Chief Engineers, of St. Louis. He contributed occasional papers to *Power* and *American Machinist*. He was especially fond of opera and vocal music and enjoyed water sports and fishing.

Mr. Stiles is survived by his widow, Marcelina F. (Ryan) Stiles, whom he married in 1930.

GEORGE EDWIN TAYLOR (1886–1936)

George Edwin Taylor, district manager at San Francisco, Calif., for the Chain Belt Company of Milwaukee, died on July 23, 1936. He had been associated with the company since 1923.

Mr. Taylor was born in Chicago, Ill., on January 22, 1886, son of Edwin and Lilla (Knight) Taylor. He took a three-year technical course at the Crane Technical High School and Junior College in Chicago (1901–1903) and an evening course in mechanical drawing at the Chicago Technical College in 1905–1906. After leaving high school he was employed successively in the shops of the Western Electric Company and by the Arthur Frantzen Company, electrical contractors, Chicago, for several years, then became a junior draftsman with the H. W. Caldwell & Son Co., Chicago, where he remained until April, 1912. He then took the position of chief draftsman for the Meese & Gottfried Co., of San Francisco. Subsequently he was put in charge of all work in the engineering department. He helped to develop a full line of power transmitting machinery, embodying friction clutch design, chain, gear, and belt drives. In a letter written in 1921 he mentioned several examples of his work, as follows:

"I have had the pleasure of seeing the successful operation of truck conveyors installed at the Bay piers for unloading ships for the California Navigation and Improvement Company, also large conveying systems for handling sugar for the California and Hawaiian Sugar Refining Company at Crockett, Calif. I have made complete layouts of timber structure and large rock screens for gravel plants such as were installed for the Grant Rock and Gravel Company at Fresno and the Grant Gravel Company at Pleasanton, Calif. We have just completed and shipped five self-propelled automatic trippers for belt conveyors to be used at the Shasta Zinc and Copper Company's plant."

During his years with this company Mr. Taylor also gave evening instruction in mathematics at the Healds Engineering School in San Francisco. In 1921 he joined the R. & J. Dick Co., Inc., of Passaic, N.J., as sales engineer, and he continued in that work until he entered the employ of the Chain Belt Company in 1923.

Mr. Taylor married Anita Leith, of San Francisco, and is survived by her. He enjoyed music, was a baseball, basketball, and football fan, and liked to fish and hunt. He was a charter member of the Cleveland Lodge No. 211, F. & A.M., Chicago, Ill., held the 32d degree in the Scottish Rite, San Francisco Consistory, and was a member of Islam Temple, A.A.O.N.M.S., San Francisco. He became a junior member of the A.S.M.E. in 1919, was advanced to the grade of associate-member in 1921, and automatically transferred to full membership in 1935.

ROGER TAYLOR (1881–1937)

Roger Taylor, superintendent of the plant of the Susquehanna Electric Company at Conowingo, Md., died on April 27, 1937. Mr. Taylor was born on October 7, 1881, at Ashton-under-Lyne, England, the son of Jesse and Mary Schofield Taylor. He received his professional education at the technical school in Ashton-under-Lyne, and later took two years' work in the Drexel Institute of Philadelphia, Pa.

Mr. Taylor's first employment after coming to the United States began in October, 1898, in the Motive Power Department of the Philadelphia (Pa.) Rapid Transit Company, where he worked on boiler and turbine tests and indicating steam engines until August, 1906, when he was appointed engineer-in-charge and assistant for several of the company's reciprocating and turbine plants.

In October, 1912, he joined the Philadelphia Suburban Gas & Electric Co. as superintendent of plants in Pottstown and Phoenixville, Pa. This assignment covered the parallel operation of turbine, hydroelectric, and reciprocating engine plants, considerable new construction, and work on gas plant operation.

In October, 1916, Mr. Taylor joined the Operating Department of the Philadelphia Electric Company. He assisted in the design and construction of the company's Delaware station and served as its superintendent. He also was closely connected with the engineering design and development of the Conowingo hydroelectric project. He remained with this company for nearly ten years, when he became associated with the Susquehanna Electric Company, a subsidiary of the Philadelphia Electric Company, as plant superintendent, which position he held for the remainder of his life.

Mr. Taylor became an associate-member of the A.S.M.E. in 1917 and was promoted to member in 1927. He also belonged to the American Institute of Electrical Engineers. He served on the National Hydraulic Committee of the National Electric Light Association and on the Prime Movers and Hydraulic Committees of the Pennsylvania Electric Association, which represented the eastern geographic division of the N.E.L.A. prior to 1933.

Although born in England, he came a citizen of the United States by his father's naturalization. He married Sarah McIlhenny, of Philadelphia, in 1906, and is survived by her and by their two children, Roger S., an electrical engineer, and S. Eleanor Taylor. Mr. Taylor's brother, Jesse Taylor, Jr., is a member of the A.S.M.E.

CARL CLAPP THOMAS (1872–1938)

Dr. Carl Clapp Thomas died at his residence at Pasadena, Calif., on June 5, 1938. He was born in Detroit, Mich., on July 14, 1872, the son of George Roscoe and Caroline Melissa (Clapp) Thomas. His preparatory education was obtained in the public schools of Detroit and later in those of Pasadena, where his father became an early resident. Carl Thomas entered in 1891 the first class at Leland Stanford University, along with the Hon. Herbert Hoover and others who have since been outstanding personalities in American life. In 1894 he transferred to Cornell University, from which he received the degree of Mechanical Engineer in 1895. In 1937, The Johns Hopkins University honored him by conferring the degree of Doctor of Engineering.

Dr. Thomas was employed for four years after graduation with the Globe Iron Works Company, shipbuilders, Cleveland, Ohio, in the shops, as draftsman, as chief draftsman, and finally as chief engineer. From 1899 to 1901 he served as chief draftsman in the marine department of the Maryland Steel Company, Sparrows Point, Md. He was next professor of marine engineering and naval architecture at New York University from 1901 to 1903, and at the same time maintained a consulting practice as a marine engineer. He was assistant professor of mechanical engineering at the University of California, Berkeley, Calif., during the college year 1903–1904, at which time he served as consultant on the design and building of the U.S.S. *Nebraska*, of dredges for the North American Dredging Company, and of other ships of various types.

In the spring of 1904, the late George Westinghouse engaged Dr. Thomas to carry out some special work for him. Later in the summer Dr. Thomas became interested in the Steam Turbine Department and spent some time on the test floor before going to Cornell University that fall as professor of marine engineering. This interest in steam turbines resulted in the offering by Professor Thomas during the following year of a course of lectures on steam turbines at Cornell University, probably one of the first courses on steam turbines in America, and, later, in the writing of a textbook on steam turbines (John Wiley & Sons, Inc.) which first appeared in 1906 and which ran through four editions. At the time it was written this book formed an outstanding contribution to engineering literature.

The summer of 1905 was spent on experimental work at the General Electric Company's laboratories at Schenectady on the specific heat of superheated steam. This was followed by extensive research on this subject at Cornell which resulted in the contribution of a paper to the A.S.M.E. on "The Specific Heat of Superheated Steam" (Trans. A.S.M.E., vol. 29, 1907, p. 1021). A by-product of this research was the invention and development of the Thomas electric calorimeter for the exact measurement of the quality of wet steam. Professor Thomas spent the summer of 1906 in the steam turbine department of the Fore River Shipbuilding Company, Quincy, Mass. During 1907–1908 he served as president and manager of Thomas and Grant, engineers and boat builders, Ithaca, N.Y.

Following the death of Prof. Storm Bull, Dr. Thomas was called to the University of Wisconsin as professor of mechanical engineering in 1908 and remained until 1913, with the exception of one year spent in research in Europe. At Wisconsin he directed much research, from some of which resulted the invention of the Thomas electric gas meter that has since been used widely throughout the world. Another invention less widely known was a method of supercharging internal-combustion engines. A third contribution during this period was the design of a form of bent tube boiler that has since been widely used. Other investigations covered steam flow, steam nozzles, air measurement, properties of bearings, boiler circulation, and properties of heat insulation materials. Many technical papers were written during this period, two of which appeared in the A.S.M.E. Transactions.

In 1913 he was called to The Johns Hopkins University, Baltimore, Md., to assist in organizing the new School of Engineering and to become its first professor of mechanical engineering, which position he filled until 1920, with the exception of the war years, 1917–1919, when he was on leave of absence to serve as manager of machinery design and fabrication, American International Shipbuilding Corporation, at Hog Island, Pa. This was the largest shipyard ever constructed, and it was here that freighters and transports were built in great numbers to aid America and her Allies in World War I.

While at The Johns Hopkins University he carried on extensive experimental work, and developed devices for the cooling of water in spray ponds, for the recovery of used oil, for the low-temperature carbonization of coal, flotation methods for minerals, etc. He also invented the electric recording gas calorimeter.

In 1920, Professor Thomas moved to Pasadena and became western representative and vice-president of Dwight P. Robinson & Co., Inc., which positions he held until his death. He had a large part in the design and construction of the Seal Beach Station of the former Los Angeles Gas & Electric Co. and of the expansion of the American Potash & Chemical Co.'s plant at Trona, Calif.

Professor Thomas became associate in engineering research at the California Institute of Technology in 1925, and continued in this position until his death. One of the results of his research work at the Institute was the development of a new apparatus to separate liquids from mixtures with vapors.

The contributions of Dr. Thomas to the civic affairs of Pasadena were of no small order. He was one of the Board of City Directors of Pasadena from 1921 to 1924. He was a director and vice-president of the Pasadena Hospital. He was a director of the Pasadena Art Institute and also of the Pasadena Civic Orchestra Association.

Dr. Thomas was a member of the American Society of Naval Architects and Marine Engineers, of The Franklin Institute (from which he received the Edward Longstreth Medal in 1912 for his paper on "The Measurement of Gases," published in the November, 1911, issue of the *Journal* of The Franklin Institute), the American Gas Institute, the American Association for the Advancement of Science, and the Inventors Guild.

He joined the A.S.M.E. in 1908 and served on its Nominating Committee in 1913. From 1913 to 1917 he was a member of the Society's Special Committee on Changes in Patent Laws of the United States. He was chairman of the Committee on Air Machinery from 1916 to 1920; a member of the Main Committee on Research, 1916–1920; and a member of the Power Test Codes Committee on Steam Turbines since 1920. He was a manager of the Society from 1920 to 1923, and a delegate to the American Engineering Council during 1924–1926.

Dr. Thomas was married on July 14, 1899, to Katherine L. Nash. Mrs. Thomas and two sons, Alfred Randall and Roscoe Carl, all of Pasadena, survive him.

Dr. Thomas possessed a keen analytical mind as evidenced by his prolific research and many inventions. He was a capable engineer and an able administrator. In university work, he was an inspiring teacher and was loved by students and associates. He was devoted to good music and throughout his life played the violin with skill and great enjoyment.

Only great dynamic energy and boundless enthusiasm could have enabled Dr. Thomas, in his relatively short life, to accomplish so much in so many diverse fields. Yet, while he was highly respected as an engineer, a scientist, a teacher, and an inventor, it is Carl Thomas the man who is remembered by his friends. He had a genius for friendship. His warm interest in people, his eagerness to help without thought of self, his uncompromising devotion to the highest ideals, combined with tender sympathy and an understanding of life's problems—these are characteristics that will make all who knew him remember Carl C. Thomas as a beloved friend.—[Memorial prepared by A. G. Christie, Baltimore, Md., Fellow and Past-President, A.S.M.E.]

WILLIAM FYFE TURNBULL (1881–1937)

William Fyfe Turnbull, engineering examiner of the New York City Municipal Civil Service Commission, died on May 14, 1937.

Mr. Turnbull was born in Belleville, Ont., Can., on August 9, 1881, the son of Alexander and Mary Esther Turnbull. He prepared for college at the high school in Orange, N.J., and then attended Columbia University, where he was graduated with the A.B. degree in 1903, and took a year of graduate work, 1903–1904. He also took two years' work in mechanical engineering at the Massachusetts Institute of Technology, 1904–1905 and 1906–1907. During his college years, he had some shop experience with the H. K. Porter Co., builders of locomotives, Pittsburgh, Pa. In 1905–1906, he worked as draftsman for the Erie Railroad, and in the same capacity for the N.Y. Central R.R. in 1907.

In 1908 and 1909, Mr. Turnbull served as assistant to the treasurer of the Hampton Institute, Virginia, his work there covering also inspection of the steam and electric light plant and the sewer system. From 1909 to 1915, he was estimator and technical correspondent with the American Locomotive Company, New York, also lecturer in strength of materials for evening classes at Teachers College, Columbia University. From 1915 to 1918, he served as instructor in machine design at the University of Pennsylvania, and in 1918–1919 was attached to the U.S. Department of Labor on war service. Following this assignment, Mr. Turnbull resumed teaching, serving on the faculty of Yale University, 1919–1921, and New York University from then until September, 1927, when he was employed by the Third Avenue Railway System of the City of New York. Here he worked on shop drawings, road tests, mechanical improvements, traffic surveys, cost of operation of buses, and proposed trolley buses. In 1934 he was appointed to the New York City Municipal Civil Service Commission as engineering examiner.

Like many engineers who divided their professional labors between teaching and commercial lines, Mr. Turnbull did considerable independent and consulting work. He was licensed as a professional engineer in the State of New York in 1924. This work included surveys for the West Shore Railroad, Erie Railroad, and Central Railroad of New Jersey, for which he also checked all steel-work drawings for the Newark Bay Viaduct.

In 1916, he married Clara Kramer, of Tuckahoe, N.Y., who survives him. They had no children. Mr. Turnbull was an American citizen, having been naturalized in 1902, at Newark, N.J. He became an associate of the A.S.M.E. in 1913, but resigned in 1917. However, he was reinstated in 1923 with the grade of member. Several brief contributions by him, dealing with engineering economics, were published in *Mechanical Engineering* and he served on the Subcommittee on Economics of the Management Division of the Society in 1933–1935. He was also a member of the Society for the Promotion of Engineering Education and the New York Railroad Club.

ARTHUR WILLIAMS (1868–1937)

Arthur Williams, former vice-president of the New York Edison Company, died on April 14, 1937. Mr. Williams was born on August 14, 1868, at Norfolk, Va., the son of Rev. Christopher Stephen and Hannah Sanford (Rogers) Williams, and was educated in public and private schools in Hartford, Conn., and in New York, N.Y.

He began work in August, 1884, with the firm of Rennie & Smith, electrical contractors, New York. In February, 1885, he entered the service of the Edison Electric Illuminating Company of New York as assistant in the Chemical Meter Department, becoming superintendent of interior construction in 1887; electrician of the company later in 1887; superintendent of the third district, 1888, and of the Underground Department, 1889; general inspector, 1890, and general agent, 1893. From then on, until 1915, he exercised the function of these two positions in this company and in the New York Edison Company, into which it was merged in 1901. He was then appointed general commercial manager, and in 1924 he was made vice-president in charge of commercial relations, from which position he retired in 1928.

Besides his lifework in the electrical industry, Mr. Williams was active in many other fields. In 1917, he was appointed to the post of Federal food administrator for New York, N.Y., and served in that capacity until his resignation in 1920. During the Spanish-American War, he served as commanding officer of the New York Volunteer Defense Forces, mining New York Harbor. In 1912, he was decorated by the King of Spain, receiving the rank of Knight in the Royal Order of Isabel the Catholic, in recognition of his work in the interests of safety; and in 1926 he was made a Chevalier of the French Legion of Honor.

Mr. Williams joined the A.S.M.E. as an associate in 1915, and was a Fellow of the American Institute of Electrical Engineers. He was a past-president of the American Association for the Advancement of Science, Association of Edison Illuminating Companies, National Electric Light Association, New York Electrical Society, and American Museum of Safety, and was chairman of the Greater New York Safety Council, 1936–1937. He had served as president of the Electrical Board of Trade and of the Electrical and Industrial Exhibition, held annually at Grand Central Palace, New York, for a number of years. He was also a member of the American Academy of Political and Social Sciences, American Electrochemical Society, American Association for Labor Legislation, International Industrial Relations Association, Society of American Military Engineers, and other technical and civic organizations, as well as of many clubs. He was the author of numerous papers on municipal ownership, electrical subjects, relations with employees, and allied topics.

Mr. Williams was deeply interested in social and civic welfare. He was unmarried, and made his home in Roslyn, Long Island, of which village he was a trustee.

RUDOLF WINTZER (1873–1937)

Rudolf Wintzer was born on May 14, 1873, at Iserlohn, Westphalia, Germany. He was one of four children of Marie Koenig and Wilhelm Wintzer. During his early life, his father acquired a factory at Guetersloh, Germany, at which wagon wheels were made. Upon the death of his father, the family established a home in Berlin. Mr. Wintzer completed his education at the Technische Hochschule, Charlottenburg, and for several years worked in various machine shops and foundries in Germany. From 1896 to 1900 he worked under Professor Riedler, consulting engineer, Charlottenburg, and later became his assistant. This work related particularly to the design of pumping and blowing engines, compressions, and all kinds of machinery for mines and iron and steel works. He was also assistant at the technical high school. In 1901–1902 he had full charge of the drafting room and shop of the Stahl und Eisen Aktiengesellschaft at Hörde, Germany, manufacturing steam engines and boilers.

His work with Professor Riedler prepared him for his next position, which was with the Westinghouse Works, at Manchester, England, where he went in 1903. From there he was called to the United States by the Guggenheim interests for consultation, and after completion of his work with them, again returned to Manchester, where he was active for several years, designing and testing large gas engines. He was finally again called to the United States by the Guggenheim organization and engaged by them for carrying on work then being done at the Snow Steam Pump Works of the International Steam Pump Company, at Buffalo. In 1906 or 1907 he became chief engineer of the Power & Mining Machinery Co., at Cudahy, Wis., which in 1906 had become part of the International Steam Pump Company. During the next few years he was kept busy traveling for the company and in work at the Buffalo and the Cudahy works.

In 1911 or 1912, while seeking other employment, he contacted the Nordberg Manufacturing Company, Milwaukee, and was engaged by the Peck Concentrator Company to design a special separator, which work he carried on in the shops of the Nordberg Manufacturing Company. He was finally employed by the Nordberg Manufacturing Company, toward the end of 1912, and remained with it until his death. Between 1922 and 1924 he acted as assistant to Dr. Bruno V. Nordberg, at that time chief engineer, and upon the latter's death in 1924, Mr. Wintzer became chief engineer of the company. Having led a very active life, he was finally appointed as consulting engineer in 1935 and his assistant, Emil Grieshaber, thereupon took over his duties as chief engineer.

During his years with the Nordberg Manufacturing Company, Mr. Wintzer developed a number of interesting units. While associated with Dr. Nordberg, he detailed and carried out special designs on a very successful hydrogen compressor. With Dr. Nordberg, he also developed large rolling mill engines, and later on, when he assumed the position of chief engineer, this experience stood him in good stead. He thereafter developed the largest hydrogen compressors so far built, as well as some very heavy rolling mill engines, river boat engines, compressors, pumps, and the like. During his lifetime, he invented a number of things and held twelve patents, either in his own name or in combination with others. He was continually striving to improve any device which came to his notice and his intense interest in all mechanical means kept him active along these lines until the last.

Mr. Wintzer was of a very retiring nature, but traveled a great deal and formed many acquaintances and friends. He often spoke of the particularly happy years spent in association with Dr. Nordberg. It seems both men recognized in each other those engineering attributes which sometimes lead to lasting friendships. His death, from heart failure, occurred on December 16, 1937. He is survived by his widow, Emmy Wintzer, whom he married in 1910, and by two boys, Herman and Fred, both of whom are engineers in the employ of chemical industries in this country, and a sister living in Hamburg, Germany. He had been a member of the A.S.M.E. since 1908.

Indexes to A.S.M.E. Papers and Publications

THIS and the following pages will serve as a guide to the current publications of the A.S.M.E. during the calendar year 1940, and also to publications developed by the technical committees.

Regular Society Publications, 1940

Mechanical Engineering, monthly (see index on page RI-79)
A.S.M.E. Transactions, monthly (see index on page RI-89)
Mechanical Catalog and Directory, 1941 edition

Special Publications Issued in 1940

1939 Oil Engine Power Cost Report
1940 Proceedings of the Oil and Gas Power Division
Autobiography of an Engineer by William LeRoy Emmet
Autobiography of John Fritz

Boiler Construction Code, 1940 Edition

Locomotive Boiler Code
Low-Pressure Heating Boiler Code
Miniature Boiler Code
Power Boiler Code Including Rules for Inspection
Unfired Pressure Vessel Code
Specifications for Materials
Suggested Rules for Care of Power Boilers

Power Test Codes

Evaporating Apparatus
Steam Locomotives

Auxiliary Sections

Part 3—Temperature Measurement, Chapter 8
Part 5—Chapter 4, Flow Measurement by Means of Standardized Nozzles and Orifice Plates
Part 11—Determination of Quality of Steam

How to Find Papers Presented at 1940 A.S.M.E. Meetings

THE technical programs of the meetings of the Society and of its Professional Divisions have been published in *Mechanical Engineering* and may be located by consulting the index on pages RI-79–88. A majority of these papers were published, or will be published, in *Mechanical Engineering* or the Transactions (including the *Journal of Applied Mechanics*) and may be located by reference to the indexes of these publications. Several additional papers and reports included in these 1940 programs were not published during the year in either Transactions or *Mechanical Engineering*, but were issued in mimeographed or photo-offset form.

Complete sets of these are on file for reference purposes at the office of the Society and the Engineering Societies Library, under the title of "Miscellaneous Papers Presented at A.S.M.E. Meetings, 1940." Photostat copies of any of the papers may be secured from the Library at twenty-five cents a page to members.

Publications Developed by the Technical Committees

THE Society's technical committees, the first of which was organized many years ago and all of which have been continuously at work on codes, standards, research, and other special reports, have developed a series of publications of permanent value to the membership. The following list is presented here for record and for ready reference. This list covers the entire group of publications of these committees completed to date which are now available.

To assist the members in securing copies of these publications the sale price is also given. A discount of 10 per cent is allowed to A.S.M.E. members on standards and a 20 per cent discount on all other publications except where otherwise noted.

AMERICAN STANDARDS

Bolt, Nut, and Rivet Proportions

Large Rivets (B18.4—1937), $0.65
Plow Bolts (B18f—1928), $0.35
Round Unslotted-Head Bolts (B18.5—1939), $0.50
Slotted-Head Proportions: Machine Screws, Cap Screws, and Wood Screws (B18c—1930), $0.45
Small Rivets (B18a—1927), $0.30
Socket Set Screws and Socket-Head Cap Screws (B18.3—1936), $0.40
Tinners', Coopers', and Belt Rivets (B18g—1929), $0.35
Track Bolts and Nuts (B18d—1930), $0.40
Wrench-Head Bolts and Nuts and Wrench Openings (B18.2—1933), $0.50
Price of Set of Standards on Bolt, Nut, and Rivet Proportions, including binder, $4.55

Piping and Pipe Fittings

Brass Fittings for Flared Copper Tubes (A40.2—1936), $0.35
Cast-Iron Pipe Flanges and Flanged Fittings for 25 Lb Maximum Saturated Steam Pressure (B16b2—1931), $0.40
Cast-Iron Pipe Flanges and Flanged Fittings for 125 Lb Maximum Saturated Steam Pressure (B16a—1939), $0.60
Cast-Iron Pipe Flanges and Flanged Fittings for 250 Lb Maximum Saturated Steam Pressure (B16b—1928), $0.50
Cast-Iron Pipe Flanges and Flanged Fittings for 800 Lb Maximum Hydraulic Pressure (B16b1—1931), $0.35
Cast-Iron Soil Pipe and Fittings (A40.1—1935), $0.65
Cast-Iron Long Turn Sprinkler Fittings for 150 and 250 Lb Maximum Saturated Steam Pressure (B16g—1929), and Addendum (B16g1—1937), $0.50
Cast-Iron Screwed Fittings for 125 and 250 Lb Maximum Saturated Steam Pressure (B16d—1927), $0.35
Code for Pressure Piping (no discount) (B31.1—1935), $1.00
Face-to-Face Dimensions of Ferrous Flanged and Welding End Valves (B16.10—1939), $0.55
Malleable-Iron Screwed Fittings for 150 Lb Maximum Saturated Steam Pressure (B16c—1939), $0.50
Pipe Plugs (B16e2—1936), $0.35
Scheme for the Identification of Piping Systems (A13—1928), $0.50
Steel Pipe Flanges and Flanged Fittings for 150 to 2500 Lb Maximum Steam Service Pressure (B16e—1939), $1.25
Wrought-Iron and Wrought-Steel Pipe (B36.10—1939), $0.50

Letter and Graphical Symbols and Charts

Aeronautical Symbols (Z10e—1929), $0.35
Drawings and Drafting-Room Practice (Z14.1—1935), $0.50
Engineering and Scientific Charts for Lantern Slides (Z15.1—1932), $0.50
Graphical Symbols for Electric Power and Wiring (Z10g2—1933), $0.20

Graphical Symbols for Electrical Traction Including Railway Signaling (Z10g5—1933), $0.40
Graphical Symbols for Plumbing, Piping, Pipe Fittings and Valves, Heating and Ventilating, Heat-Power Apparatus, Conventional Rivets, etc. (Z14.2—1935), $0.45
Graphical Symbols for Radio (Z10g3—1933), $0.20
Graphical Symbols for Telephone and Telegraph Use (Z10g6—1929), $0.20
Letter Symbols for Electrical Quantities (Z10g1—1929), $0.20
Symbols for Electrical Equipment of Buildings (C10—1924), $0.20
Symbols for Heat and Thermodynamics (Z10c—1931), $0.30
Symbols for Mechanics, Structural Engineering, and Testing Materials (Z10a—1932), $0.25
Symbols for Photometry and Illumination (Z10d—1930), $0.20
Time Series Charts (Z15.2—1938), $1.25

MISCELLANY

Fire-Hose Coupling Screw Thread (B26—1925), $0.25
Production and Inspection of Fire-Hose Coupling Screw Thread (1925), $0.25
Gear Materials and Blanks (B6.2—1933), $0.50
Hose Coupling Screw Threads (B33.1—1935), $0.25
Indicating Pressure and Vacuum Gages (B40—1939), $0.40
Rolled Threads for Screw Shells of Electric Sockets and Lamp Bases (C44—1931), $0.35
Shaft Couplings (B49—1932), $0.35
Spur Gear Tooth Form (B6.1—1932), $0.45

Small Tools and Machine Tool Elements

Machine Tapers (B5.10—1937), $0.50
Milling Cutters (B5c—1930), $0.75
Taps—Cut and Ground Threads (B5.4—1939), $1.25
Terminology and Definitions for Single-Point Cutting Tools (B5.13—1939), $0.40
Adjustable Adapters (B5.11—1937), $0.50
Chucks and Chuck Jaws (B5.8—1936), $0.45
Circular and Dovetail Forming Tool Blanks (B5.7—1936), $0.40
Involute Splines, Side Bearings (B5.15—1939), $0.65
Jig Bushings (B5.6—1935), $0.35
Lathe Spindle Noses (B5.9—1936), $0.50
Rotating Air Cylinders and Adapters (B5.5—1932), $0.35
Tool Holder Shanks—Tool Post Openings (B5b—1929), $0.25
T-Slots, Their Bolts, Nuts, Tongues, and Cutters (B5a—1927), $0.35
Ball and Roller Bearings (B3.1, 2, 3—1930–1933), $0.40
Code for Design of Transmission Shafting (B17c—1927), $0.75
Shafting and Stock Keys (B17.1—1934), $0.45
Screw Threads for Bolts, Nuts, Machine Screws, and Threaded Parts (B1.1—1935), $0.60
Tolerances, Allowances, and Gages for Metal Fits (B4a—1925), $0.50
Woodruff Keys, Keyslots, and Cutters (B17f—1930), $0.35
Price of Set of Standards on Small Tools and Machine-Tool Elements, including binder, $9.85

BOILER CONSTRUCTION CODE—1940

Locomotive Boiler Code, $0.55
Low-Pressure Heating Boiler Code, $0.75
Miniature Boiler Code, $0.65
Power Boiler Code Including Rules for Inspection, $2.25
Unfired Pressure Vessel Code, $1.50
Specifications for Materials, $2.00
Suggested Rules for Care of Power Boilers, $1.00
Price of complete set of Boiler Codes including binder, $8.50
Boiler Code Interpretations
Price obtainable upon request

JOINT CODE

API-ASME Code for Unfired Pressure Vessels for Petroleum Liquids and Gases (1938 with 1940 Addenda), $1.25

POWER TEST CODES AND AUXILIARY SECTIONS

Test Codes for

Atmospheric Water-Cooling Equipment (1930), $0.45
Compressors and Exhausters (1935), $0.95
Displacement Compressors, Vacuum Pumps, and Blowers (1939), $0.75
Evaporating Apparatus (1940), $0.50
Feedwater Heaters (1927), $0.35
Gas Producers (1928), $0.55
Hydraulic Prime Movers (1938), $0.60
Internal-Combustion Engines (1930), $0.55
Liquid Fuels (1930), $0.35
Reciprocating Steam Engines (1935), $0.65
Reciprocating Steam-Driven Displacement Pumps (1927), $0.65
Refrigerating Systems (1927), $0.55
Solid Fuels (1931), $0.55
Speed-Responsive Governors (1927), $0.45
Stationary Steam-Generating Units (1936), $0.60
Steam Condensing Apparatus (1938), $0.65
Steam Locomotives (1940), $0.55

Auxiliary Sections

Definitions and Values (1931), $0.40
General Instructions (1929), $0.35
Part 1—General Consideration (1935), $0.35
Part 2—Pressure Measurement; Chapter 2, Static and Total Pressure, Static Holes and Tubes, Impact Tubes, and Chapter 3, Pipes for Pressure Measurement (1936), $0.65
Part 2—Pressure Measurement; Chapter 4, Bourdon, Bellows, Diaphragm, and Deadweight Gages (1938), $0.65
Part 3—Temperature Measurement; Chapter 1, General; Chapter 5, Pyrometric Cones; Chapter 6, Liquid-in-Glass Thermometers, and Chapter 7, Bourdon Tube Thermometers (1931), $0.75
Part 3—Temperature Measurement; Chapter 2, Radiation Pyrometers (1936), $0.55
Part 3—Temperature Measurement; Chapter 8, Optical Pyrometers (1940), $0.35
Part 4—Head Measuring Apparatus (1933), $0.35
Part 5, Chapter 4—Flow Measurement by Means of Standardized Nozzles and Orifice Plates (1940), $2.75
Part 6—Electrical Measurements (1934), $1.25
Part 9—Heat of Combustion (1932), $0.40
Part 10—Flue and Exhaust Gas Analyses (1936), $1.35
Part 11—Determination of Quality of Steam (1931), $0.45
Part 12—Measurement of Time (1932), $0.35
Part 13—Speed Measurements (1939), $0.45
Part 14—Linear Measurements (1936), $0.55
Part 15—Measurement of Surface Areas (1937), $0.75
Part 16—Density Determinations (1931), $0.30
Part 17—Determination of the Viscosity of Liquids (1931), $0.45
Part 18—Humidity Determinations (1932), $0.50
Part 20—Smoke-Density Determinations (1936), $0.65
Part 21—Leakage Measurement, Chapter 1, Condenser Leakage Tests (1928), $0.35
Part 21—Leakage Measurement; Chapter 2, Boiler and Piping; Chapter 3, Steam Engine Leakage (1932), $0.35

RESEARCH

Dynamic Loads on Gear Teeth (1932), $1.50
Fluid Meters:
Part 1—Theory and Application (1937), $3.00
Part 2—Description of Meters (1931), $1.75
Part 3—Selection and Installation (1933), $1.50
Report of the AGA-ASME Committee on Orifice Coefficients (1935), $2.75
Tests on Electrical Equipment for Drilling Rotary Drilled Oil Wells (1933), $0.85
Tests on Steam Equipment for Drilling Rotary Drilled Oil Wells (1932), $0.85
Bibliography on Cutting of Metals (1866–1930), $1.25
Bibliography on Deterioration of Condensing Equipment (1845–1930), $1.25
Bibliography on Effect of Temperature Upon Properties of Metals (1928–1931), $1.25
Bibliography on Management Literature and Supplement (1903–1935), $2.75
Bibliography on Mechanical Springs (1678–1927), $1.25
Bibliography on Woods of the World (1928), $1.25
Bibliography on Marketing Research (1935), $1.00
Bibliography on Machining of Wood (1939) $1.25

SAFETY CODES

Safety Code for Elevators (A17.1—1937) (10 per cent discount), $1.00
Elevator Inspectors' Manual (A17.2—1937) (10 per cent discount), $0.75
Safety Code for Mechanical Power-Transmission Apparatus (10 per cent discount) (B15—1927), $0.35
Compressed-Air Machinery and Equipment (B19—1938), $0.30

BIOGRAPHIES

BIOGRAPHIES issued under the sponsorship of the A.S.M.E. Biography Advisory Committee are as follows:

Autobiography of John A. Brashear (1924), $5.00
Autobiography of an Engineer, by W. LeR. Emmet (1940), $3.50
Autobiography of John Frits (1940), $3.25
Biography of James Hartness, by Joseph W. Roe (1937), $4.00
Biography of John Stevens, by Archibald Douglas Turnbull (1928), $5.00
Biography of John Edson Sweet, by A. W. Smith (1925), $4.50
Biography of Robert Henry Thurston, by William F. Durand (1929), $5.00
Life of Henry Laurence Gantt, by L. P. Alford (1934), $5.00

BOOKS ON SPECIAL SUBJECTS

Aeronautical Dictionary (1929), $1.65
Corrosion-Resistant Metals (1936), $1.25
Engineering's Part in the Development of Civilization (1939), $1.50
General Discussion on Lubrication (1938) (no discount), $6.50
Hydraulic Laboratory Practice (1929), $10.00
Hydraulic Structures (1937), $18.00
Manual on Cutting of Metals (1939), $5.00
1941 A.S.M.E. Mechanical Catalog and Directory, $3.00 (sent gratis to members, upon request)
1939 Oil Engine Power Cost Report (1940), $1.00
Theoretical Steam Rate Tables (1937), $1.25
